### **Executive Summary**

1. Stock: red king crab (RKC), *Paralithodes camtschaticus*, in Bristol Bay, Alaska.
2. Catches: The domestic RKC fishery began to expand in the late 1960s and peaked in 1980 with a catch of 129.95 million lbs (58,943 t). The catch declined dramatically in the early 1980s and remained at low levels during the last three decades. Catches during recent years until 2010/11 were among the high catches in last 15 years. The retained catch in 2015/16 was about 10 million lbs (4,500 t), similar to the catch in 2014/15. The magnitude of bycatch from groundfish trawl fisheries has been stable and small relative to stock abundance during the last 10 years.
3. Stock biomass: Estimated mature biomass increased dramatically in the mid 1970s and decreased precipitously in the early 1980s. Estimated mature crab abundance had increased during 1985-2009 with mature females being about three times more abundant in 2009 than in 1985 and mature males being about two times more abundant in 2009 than in 1985. Estimated mature abundance has steadily declined since 2009.
4. Recruitment: Estimated recruitment was high during 1970s and early 1980s and has generally been low since 1985 (1979 year class). During 1984-2016, only in 1984, 1986, 1995, 1999, 2002 and 2005 were estimated recruitments above the historical average for 1976-2016. Estimated recruitment was extremely low during the last nine years.
5. Management performance:

Status and catch specifications (1,000 t) (scenario 2):

<b>Year</b>	<b>MSST</b>	<b>Biomass (MMB)</b>	<b>TAC</b>	<b>Retained Catch</b>	<b>Total Catch</b>	<b>OFL</b>	<b>ABC</b>
2012/13	13.19 <sup>A</sup>	29.05 <sup>A</sup>	3.56	3.62	3.90	7.96	7.17
2013/14	12.85 <sup>B</sup>	27.12 <sup>B</sup>	3.90	3.99	4.56	7.07	6.36
2014/15	13.03 <sup>C</sup>	27.25 <sup>C</sup>	4.49	4.54	5.44	6.82	6.14
2015/16	12.89 <sup>D</sup>	27.68 <sup>D</sup>	4.52	4.61	5.34	6.73	6.06
2016/17		24.00 <sup>D</sup>				6.64	5.97

The stock was above MSST in 2015/16 and hence was not overfished. Overfishing did not occur.

Status and catch specifications (million lbs):

<b>Year</b>	<b>MSST</b>	<b>Biomass (MMB)</b>	<b>TAC</b>	<b>Retained Catch</b>	<b>Total Catch</b>	<b>OFL</b>	<b>ABC</b>
2012/13	29.1 <sup>A</sup>	64.0 <sup>A</sup>	7.85	7.98	8.59	17.55	15.80
2013/14	28.3 <sup>B</sup>	59.9 <sup>B</sup>	8.60	8.80	10.05	15.58	14.02
2014/15	28.7 <sup>C</sup>	60.1 <sup>C</sup>	9.99	10.01	11.99	15.04	13.53
2015/16	28.4 <sup>D</sup>	61.0 <sup>D</sup>	9.97	10.17	11.77	14.84	13.36
2016/17		52.9 <sup>D</sup>				14.63	13.17

Notes:

A – Calculated from the assessment reviewed by the Crab Plan Team in September 2013

B – Calculated from the assessment reviewed by the Crab Plan Team in September 2014

C – Calculated from the assessment reviewed by the Crab Plan Team in September 2015

D – Calculated from the assessment reviewed by the Crab Plan Team in September 2016

## 6. Basis for the OFL: All table values are in 1000 t (Scenario 2):

<b>Year</b>	<b>Tier</b>	<b>B<sub>MSY</sub></b>	<b>Current MMB</b>	<b>B/B<sub>MSY</sub> (MMB)</b>	<b>F<sub>OFL</sub></b>	<b>Years to define B<sub>MSY</sub></b>	<b>Natural Mortality</b>
2012/13	3b	27.5	26.3	0.96	0.31	1984-2012	0.18
2013/14	3b	26.4	25.0	0.95	0.27	1984-2013	0.18
2014/15	3b	25.7	24.7	0.96	0.28	1984-2014	0.18
2015/16	3b	26.1	24.7	0.95	0.27	1984-2015	0.18

Basis for the OFL: All table values are in million lbs:

Year	Tier	B <sub>MSY</sub>	Current MMB	B/B <sub>MSY</sub> (MMB)	F <sub>OFL</sub>	Years to define B <sub>MSY</sub>	Natural Mortality
2012/13	3b	60.7	58.0	0.96	0.31	1984-2012	0.18
2013/14	3b	58.2	55.0	0.95	0.27	1984-2013	0.18
2014/15	3b	56.7	54.4	0.96	0.28	1984-2014	0.18
2015/16	3b	57.5	54.4	0.95	0.27	1984-2015	0.18
2016/17	3b	56.8	52.9	0.93	0.27	1984-2016	0.18

## A. Summary of Major Changes

**1. Change to management of the fishery:** None.

**2. Changes to the input data:**

- a. The new 2016 NMFS trawl survey data and BSFRF side-by-side trawl survey data during 2013-2016 were used.
- b. Catch and biomass data were updated to include the 2015/16 information.
- c. Total NMFS survey biomass CVs were updated and they are slightly different from those in 2015 for some years.

**3. Changes to the assessment methodology:**

- a. Three model scenarios are evaluated in this report (See Section E.3.a for details):

Scenario 1: the same as Scenario 1 in the SAFE report in September 2015 using BSFRF survey data in 2007 and 2008. The BSFRF survey is treated as an independent survey, and no assumption is made about the capture probabilities of the BSFRF survey. In effect, survey selectivities for both surveys are estimated separately and directly in the model. A survey capture probability for a length group is simply defined as the proportion of the crab in the length group within the area-swept that is caught by the survey net.

Scenario 1n: the same as scenario 1 plus additional BSFRF survey data in 2013-2016.

Scenario 2: the same as scenario 1n except for the assumption that BSFRF survey capture probabilities are 1.0 for all length groups. Under this assumption, NMFS survey selectivities are the products of crab availabilities (equal to BSFRF survey selectivities) and NMFS survey capture probabilities.

- b. A jittering approach is used to find the optimum.

**4. Changes to assessment results:**

The population biomass estimates in 2016 are slightly lower than those in 2015. Among the three scenarios, model estimated relative survey biomasses are very similar. The absolute population biomass estimates are slightly higher for scenario 2 than for scenario 1n. Scenario 1n is higher

than scenario 1 during recent years, due to use of the BSFRF survey data (2013-2016) for scenarios 1n and 2.

## ***B. Responses to SSC and CPT Comments***

### **1. Responses to the most recent two sets of SSC and CPT comments on assessments in general:**

None.

### **2. Responses to the most recent two sets of SSC and CPT comments specific to this assessment:**

#### **Response to CPT Comments (from September 2015)**

*"The CPT recommends that size composition and biomass estimates from the 2013-2015 BSFRF side-by-side surveys be included in the assessment model. Sufficient data from these surveys are now available to help inform catchability of the NMFS trawl survey. The CPT identified several approaches, such as considering these surveys as an extension of the BSFRF surveys in 2007 and 2008, which are already used in the model. The earlier surveys did not use the side-by-side design, so technical aspects considerations of this approach would need to be evaluated. Another approach would be to drop the 2007 and 2008 surveys, and to add the 2013-2015 surveys. Since size composition data were collected during 2013-2015 surveys, it should be possible to evaluate survey selectivity, which needed to be assumed for 2007-2008 surveys. Due to the amount of analysis required to incorporate a new survey time series into the model, Jie did not think that this would be ready for review at the May 2016 CPT meeting."*

These comments were addressed in May 2016.

#### **Response to CPT Comments (from January 2016)**

*"CPT requests to the Bristol Bay red king crab assessment authors for May 2016 meeting: The CPT requested two assessments in which data from the 2007 and 2008 BSFRF surveys and the 2013–2015 BSFRF side-by-side are used to estimate trawl survey selectivity using the aforementioned snow crab model “separate survey” approach: one assessment without a prior for survey Q from the Otto-Somerton double-bag study; one assessment with a prior for survey Q from the double-bag study. The CPT also recommended that an approach be developed where the paired design of 2013-2015 BSFRF surveys is used to directly estimate selectivity. This would involve adding size-structured tow-by-tow data in new likelihood component in the assessment model, and was considered as a project for model development. There was no expectation by the CPT that such a model would be a candidate base model for review at the May CPT meeting."*

These comments were addressed in May 2016.

### **Response to CPT Comments (from May 2016)**

*"The CPT had several comments about this approach. First, it was noted at NMFS/BSRF ratios were highly variable, and that a better approach would be to consider the ratio of the NMFS survey to the sum of two surveys NMFS/(NMFS+BSFRF). Second, an attempt should be made to fit actual tow-by-tow data rather than survey aggregates. Finally, catchability for the NMFS survey was estimated to be greater than one for some model runs (this only occurred when the prior was omitted). It was suggested that catchability could be limited to values less than one by parameterizing catchability on a logit scale. The CPT concluded that these issues needed to be addressed before scenario 3 could be adopted."*

The ratio of the NMFS survey to the sum of two surveys NMFS/(NMFS+BSFRF) was also evaluated in May 2016 and the results were not presented to the CPT meeting but were added to the final draft report. We agree that this approach is better than the NMFS/BSRF ratios.

Due to very small amount of crab caught in each tow, it is not feasible to fit the actual tow-by-tow data.

We will examine the approach to parameterize catchability on a logit scale so that it is less or equal to 1.0 in the future work (May 2017).

*"The CPT requests that the following models be brought forward in September 2016: scenario 1 (status quo), scenario 1n, and scenario 2. Since results from the 2016 BSFRF survey will be available on the same timetable as the 2016 NMFS survey, these data should be incorporated into scenarios 1n and 2."*

These three scenarios are presented in the September 2016 SAFE report.

### **Response to SSC Comments specific to this assessment (from October 2015)**

*"The SSC reiterates its previous concern that improvement in model fit by increasing M is not a sufficient condition for accepting Model 1. The SSC reiterates its previous recommendation that the author should test the hypothesis that natural mortality varies annually due to environmental change by running a research model with a random walk on M and then statistically evaluating relationships between time trends in estimated M relative to plausible mechanisms influencing M. We agree that this model should not be used for setting biological reference points, however it may provide useful information on the appropriate time stanzas for time varying M. Mechanistic explanations for the resulting time stanzas could then be explored."*

*The SSC agrees with the CPT that the author should explore a model that incorporates the 2013-2015 side-by-side BSFRF data."*

The side-by-side data were evaluated in May 2016. We have spent considerable time over last 20 years to identify mechanisms for change in natural mortality over time but without much success. It is a very complex problem and many factors might have played a role on it. We will continue to work on this issue in the future.

### **Response to SSC Comments specific to this assessment (from June 2016):**

*"The SSC supports the CPT recommendation to bring forward three scenarios for the stock assessment in fall 2016: (1) scenario 1, which is the status quo (2015) using BSFRF data from 2007 ad 2008 in which the two surveys are treated as independent surveys and survey selectivities are estimated separately and directly in the model; (2) scenario 1n, which is the same as scenario 1 but also includes the 2013-2015 BSFRF survey data, and (3) scenario 2, which is the same as scenario 1n but assumes that the BSFRF survey has capture probabilities of 1.0 for all length groups.*

*When these scenarios are presented, the terms "capture probabilities" and "selectivity" should be clearly defined. In the report, their descriptions seemed somewhat confusing and contradictory. For instance, Figure 6 implies catchabilities at small sizes in the BSFRF survey that are less than 1.0 for all scenarios, but from the text, this should not be the case. It is important that the definitions and procedures are clearly described."*

We reported the results of these three scenarios in this SAFE report and cleaned up the confusion of terms "capture probabilities" and "selectivity" throughout the report.

## **C. Introduction**

### **1. Species**

Red king crab (RKC), *Paralithodes camtschaticus*, in Bristol Bay, Alaska.

### **2. General distribution**

Red king crab inhabit intertidal waters to depths >200 m of the North Pacific Ocean from British Columbia, Canada, to the Bering Sea, and south to Hokkaido, Japan, and are found in several areas of the Aleutian Islands, eastern Bering Sea, and the Gulf of Alaska.

### **3. Stock Structure**

The State of Alaska divides the Aleutian Islands and eastern Bering Sea into three management registration areas to manage RKC fisheries: Aleutian Islands, Bristol Bay, and Bering Sea (Alaska Department of Fish and Game (ADF&G) 2012). The Bristol Bay area includes all waters north of the latitude of Cape Sarichef (54°36' N lat.), east of 168°00' W long., and south of the latitude of Cape Newenham (58°39' N lat.) and the fishery for RKC in this area is managed separately from fisheries for RKC outside of this area; i.e., the red king crab in the Bristol Bay

area are assumed to be a separate stock from red king crab outside of this area. This report summarizes the stock assessment results for the Bristol Bay RKC stock.

#### **4. Life History**

Red king crab have a complex life history. Fecundity is a function of female size, ranging from several tens of thousands to a few hundreds of thousands (Haynes 1968; Swiney et al. 2012). The eggs are extruded by females, fertilized in the spring, and held by females for about 11 months (Powell and Nickerson 1965). Fertilized eggs are hatched in the spring, most during April-June (Weber 1967). Primiparous females are bred a few weeks earlier in the season than multiparous females.

Larval duration and juvenile crab growth depend on temperature (Stevens 1990; Stevens and Swiney 2007). Male and female RKC mature at 5–12 years old, depending on stock and temperature (Loher et al. 2001; Stevens 1990) and may live >20 years (Matsuura and Takeshita 1990). Males and females attain a maximum size of 227 and 195 mm carapace length (CL), respectively (Powell and Nickerson 1965). Female maturity is evaluated by the size at which females are observed to carry egg clutches. Male maturity can be defined by multiple criteria including spermatophore production and size, chelae vs. carapace allometry, and participation in mating *in situ* (reviewed by Webb 2014). For management purposes, females >89 mm CL and males >119 mm CL are assumed to be mature for Bristol Bay RKC. Juvenile RKC molt multiple times per year until age 3 or 4; thereafter, molting continues annually in females for life and in males until maturity. Male molting frequency declines after attaining functional maturity.

#### **5. Fishery**

The RKC stock in Bristol Bay, Alaska, supports one of the most valuable fisheries in the United States. A review of the history of the Bristol Bay RKC fishery is provided in Fitch et al. (2012) and Otto (1989). The Japanese fleet started the fishery in the early 1930s, stopped fishing from 1940 to 1952, and resumed the fishery from 1953 until 1974. The Russian fleet fished for RKC from 1959 to 1971. The Japanese fleet employed primarily tanglenets with a very small proportion of catch from trawls and pots. The Russian fleet used only tanglenets. United States trawlers started fishing Bristol Bay RKC in 1947, but the effort and catch declined in the 1950s. The domestic RKC fishery began to expand in the late 1960s and peaked in 1980 with a catch of 129.95 million lbs (58,943 t), worth an estimated \$115.3 million ex-vessel value. The catch declined dramatically in the early 1980s and has remained at low levels during the last two decades (Table 1). After the early 1980s stock collapse, the Bristol Bay RKC fishery took place during a short period in the fall (usually lasting about a week) with the catch quota based on the stock assessment conducted the previous summer (Zheng and Kruse 2002). Beginning with the 2005/2006 season, new regulations associated with fishery rationalization resulted in an increase in the duration of the fishing season (October 15 to January 15). With the implementation of crab rationalization, historical guideline harvest levels (GHL) were changed to a total allowable catch (TAC). Before rationalization, the implementation errors were quite high for some years and total actual catch from 1980 to 2007 was about 6% less than the sum of GHL/TAC over that period.

## **6. Fisheries Management**

King and Tanner crab stocks in the Bering Sea and Aleutian Islands are managed by the State of Alaska through a federal king and Tanner crab fishery management plan (FMP). Under the FMP, management measures are divided into three categories: (1) fixed in the FMP, (2) frame worked in the FMP, and (3) discretion of the State of Alaska. The State of Alaska is responsible for determining and establishing the GHL/TAC under the framework in the FMP.

Harvest strategies for the Bristol Bay RKC fishery have changed over time. Two major management objectives for the fishery are to maintain a healthy stock that ensures reproductive viability and to provide for sustained levels of harvest over the long term (ADF&G 2012). In attempting to meet these objectives, the GHL/TAC is coupled with size-sex-season restrictions. Only males  $\geq$ 6.5-in carapace width (equivalent to 135-mm carapace length, CL) may be harvested and no fishing is allowed during molting and mating periods (ADF&G 2012). Specification of TAC is based on a harvest rate strategy. Before 1990, harvest rates on legal males were based on population size, abundance of prerecruits to the fishery, and postrecruit abundance, and rates varied from less than 20% to 60% (Schmidt and Pengilly 1990). In 1990, the harvest strategy was modified, and a 20% mature male harvest rate was applied to the abundance of mature-sized ( $\geq$ 120-mm CL) males with a maximum 60% harvest rate cap of legal ( $\geq$ 135-mm CL) males (Pengilly and Schmidt 1995). In addition, a minimum threshold of 8.4 million mature-sized females ( $\geq$ 90-mm CL) was added to existing management measures to avoid recruitment overfishing (Pengilly and Schmidt 1995). Based on a new assessment model and research findings (Zheng et al. 1995a, 1995b, 1997a, 1997b), the Alaska Board of Fisheries adopted a new harvest strategy in 1996. That strategy had two mature male harvest rates: 10% when effective spawning biomass (ESB) is between 14.5 and 55.0 million lbs and 15% when ESB is at or above 55.0 million lbs (Zheng et al. 1996). The maximum harvest rate cap of legal males was changed from 60% to 50%. A threshold of 14.5 million lbs of ESB was also added. In 1997, a minimum threshold of 4.0 million lbs was established as the minimum GHL for opening the fishery and maintaining fishery manageability when the stock abundance is low. The Board modified the current harvest strategy by adding a mature harvest rate of 12.5% when the ESB is between 34.75 and 55.0 million lbs in 2003 and eliminated the minimum GHL threshold in 2012. The current harvest strategy is illustrated in Figure 1.

## **D. Data**

### **1. Summary of New Information**

The NMFS and BSFRF trawl survey data were updated to include the survey data in 2016.

Catch and biomass data were updated to 2015/16.

Data types and ranges are illustrated in Figure 2.

### **2. Catch Data**

Data on landings of Bristol Bay RKC by length and year and catch per unit effort from 1960 to 1973 were obtained from annual reports of the International North Pacific Fisheries Commission (Hoopes et al. 1972; Jackson 1974; Phinney 1975) and from the ADF&G from 1974 to 2015. Bycatch data are available starting from 1990 and were obtained from the ADF&G observer

database and reports (Gaeuman 2013). Sample sizes for catch by length and shell condition are summarized in Table 2. Relatively large samples were taken from the retained catch each year. Sample sizes for trawl bycatch were the annual sums of length frequency samples in the National Marine Fisheries Service (NMFS) database.

#### ***(i). Catch Biomass***

Retained catch and estimated bycatch biomasses are summarized in Table 1 and illustrated in Figure 2. Retained catch and estimated bycatch from the directed fishery include the general, open-access fishery (prior to rationalization), or the individual fishery quota (IFQ) fishery (after rationalization), as well as the Community Development Quota (CDQ) fishery and the ADF&G cost-recovery harvest. Starting in 1973, the fishery generally occurred during the late summer and fall. Before 1973, a small portion of retained catch in some years was caught from April to June. Because most crab bycatch from the groundfish trawl fisheries occurred during the spring, the years in Table 1 are one year less than those from the NMFS trawl bycatch database to approximate the annual bycatch for reporting years defined as June 1 to May 31; e.g., year 2002 in Table 1 for trawl bycatch corresponds to what is reported for year 2003 in the NMFS database. Catch biomass is shown in Figure 3. Bycatch data for the cost-recovery fishery before 2006 were not available. In this report, pot fisheries include both the directed fishery and RKC bycatch in the Tanner crab pot fishery and trawl fisheries are groundfish trawl fisheries.

#### ***(ii). Catch Size Composition***

Retained catch by length and shell condition and bycatch by length, shell condition, and sex were obtained for stock assessments. From 1960 to 1966, only retained catch length compositions from the Japanese fishery were available. Retained catches from the Russian and U.S. fisheries were assumed to have the same length compositions as the Japanese fishery during this period. From 1967 to 1969, the length compositions from the Russian fishery were assumed to be the same as those from the Japanese and U.S. fisheries. After 1969, foreign catch declined sharply and only length compositions from the U.S. fishery were used to distribute catch by length.

#### ***(iii). Catch per Unit Effort***

Catch per unit effort (CPUE) is defined as the number of retained crab per tan (a unit fishing effort for tanglenets) for the Japanese and Russian tanglenet fisheries and the number of retained crab per potlift for the U.S. fishery (Table 1). Soak time, while an important factor influencing CPUE, is difficult to standardize. Furthermore, complete historical soak time data from the U.S. fishery are not available. Based on the approach of Balsiger (1974), all fishing effort from Japan, Russia, and U.S. were standardized to the Japanese tanglenet from 1960 to 1971, and the CPUE was standardized as crab per tan. Except for the peak-to-crash years of late 1970s and early 1980s the correspondence between U.S. fishery CPUE and area-swept survey abundance is poor (Figure 4). Due to the difficulty in estimating commercial fishing catchability and crab availability to the NMFS annual trawl survey data, commercial CPUE data were not used in the model.

### **3. NMFS Survey Data**

The NMFS has performed annual trawl surveys of the eastern Bering Sea since 1968. Two vessels, each towing an eastern otter trawl with an 83 ft headrope and a 112 ft footrope, conducted this multispecies, crab-groundfish survey during the summer. Stations were sampled in the center of a systematic 20 X 20 nm grid overlaid in an area of  $\approx 140,000 \text{ nm}^2$ . Since 1972, the trawl survey has covered the full stock distribution except in nearshore waters. The survey in Bristol Bay occurs primarily during late May and June. Tow-by-tow trawl survey data for Bristol Bay RKC during 1975-2016 were provided by NMFS.

Abundance estimates by sex, carapace length, and shell condition were derived from survey data using an area-swept approach (Figures 5a and 5b). Spatial distributions of crab from the standard trawl surveys during recent years are shown in Appendix B. Until the late 1980s, NMFS used a post-stratification approach, but subsequently treated Bristol Bay as a single stratum; the estimates shown for Bristol Bay in Figures 4 and 5 were made without post-stratification. If multiple tows were made for a single station in a given year, the average of the abundances from all tows within that station was used as the estimate of abundance for that station. The new time series since 2015 discards all “hot spot” tows. We used the new area-swept estimates provided by NMFS in 2016.

In addition to standard surveys, NMFS also conducted some surveys after the standard surveys to better assess mature female abundance. In addition to the standard surveys conducted in early June (late May to early June in 1999 and 2000), a portion of the distribution of Bristol Bay RKC was resurveyed in 1999, 2000, and 2006-2012. Resurveys performed in late July, about six weeks after the standard survey, included 31 stations (1999), 23 stations (2000), 31 stations (2006, 1 bad tow and 30 valid tows), 32 stations (2007-2009), 23 stations (2010) and 20 stations (2011 and 2012) with high female density. The resurveys were necessary because a high proportion of mature females had not yet molted or mated when sampled by the standard survey. Differences in area-swept estimates of abundance between the standard surveys and resurveys of these same stations are attributed to survey measurement errors or to seasonal changes in distribution between survey and resurvey. More large females were observed in the resurveys than during the standard surveys in 1999 and 2000 because most mature females had not molted prior to the standard surveys. As in 2006, area-swept estimates of males >89 mm CL, mature males, and legal males within the 32 resurvey stations in 2007 were not significantly different ( $P=0.74$ , 0.74 and 0.95; paired *t*-test of sample means) between the standard survey and resurvey tows. However, similar to 2006, area-swept estimates of mature females within the 32 resurvey stations in 2007 were significantly different ( $P=0.03$ ; paired *t*-test) between the standard survey and resurvey tows. Resurvey stations were close to shore during 2010-2012, and mature and legal male abundance estimates were lower for the re-tow than the standard survey. Following the CPT recommendation, we used the standard survey data for male abundance estimates and only the resurvey data, plus the standard survey data outside the resurveyed stations, to assess female abundances during these resurvey years.

### **4. Bering Sea Fisheries Research Foundation Survey Data**

The BSFRF conducted trawl surveys for Bristol Bay RKC in 2007 and 2008 with a small-mesh trawl net and 5-minute tows. The surveys occurred at similar times as the NMFS standard surveys and covered about 97% of the Bristol Bay area. Few Bristol Bay RKC were found

outside of the BSFRF survey area. Because of the small mesh size, the BSFRF surveys were expected to catch more of RKC within the swept area. Crab abundances of different size groups were estimated by the kriging method. Mature male abundances were estimated to be 22.331 in 2007 and 19.747 million in 2008 with respective CVs of 0.0634 and 0.0765. BSFRF also conducted side-by-side survey with NMFS trawl survey during 2013-2016 in Bristol Bay.

## ***E. Analytic Approach***

### **1. History of Modeling Approaches**

To reduce annual measurement errors associated with abundance estimates derived from the area-swept method, ADF&G developed a length-based analysis (LBA) in 1994 that incorporates multiple years of data and multiple data sources in the estimation procedure (Zheng et al. 1995a). Annual abundance estimates of the Bristol Bay RKC stock from the LBA have been used to manage the directed crab fishery and to set crab bycatch limits in the groundfish fisheries since 1995 (Figure 1). An alternative LBA (research model) was developed in 2004 to include small size groups for federal overfishing limits. The crab abundance declined sharply during the early 1980s. The LBA estimated natural mortality for different periods of years, whereas the research model estimated additional mortality beyond a basic constant natural mortality during 1976-1993. In this report, we present only the research model that was fit to the data from 1975 to 2016.

### **2. Model Description**

The original LBA model was described in detail by Zheng et al. (1995a, 1995b) and Zheng and Kruse (2002). The model combines multiple sources of survey, catch, and bycatch data using a maximum likelihood approach to estimate abundance, recruitment, selectivities, catches, and bycatch of the commercial pot fisheries and groundfish trawl fisheries. A full model description is provided in Appendix A.

a-f. See appendix A.

g. Critical assumptions of the model:

- i. The base natural mortality is constant over shell condition and length and was estimated assuming a maximum age of 25 and applying the 1% rule (Zheng 2005).
- ii. Survey and fisheries selectivities are a function of length and were constant over shell condition. Selectivities are also a function of sex except for trawl bycatch selectivities, which are the same for both sexes. Two different survey selectivities were estimated: (1) 1975-1981 and (2) 1982-2016, based on modifications to the trawl gear used in the assessment survey.
- iii. Growth is a function of length and is assumed to not change over time for males. For females, growth-per-molt increments as a function of length were estimated for three periods (1975-1982, 1983-1993, and 1994-2016) based on sizes at maturity. Once mature, female red king crab grow with a much smaller growth increment per molt.

- iv. Molting probabilities are an inverse logistic function of length for males. Females molt annually.
- v. Annual fishing seasons for the directed fishery are short.
- vi. The prior of survey catchability ( $Q$ ) was estimated to be 0.896, based on a trawl experiment by Weinberg et al. (2004) with a standard deviation of 0.025.  $Q$  is assumed to be constant over time and is estimated in the model.
- vii. Males mature at sizes  $\geq 120$  mm CL. For convenience, female abundance was summarized at sizes  $\geq 90$  mm CL as an index of mature females.
- viii. Measurement errors were assumed to be normally distributed for length compositions and were log-normally distributed for biomasses.
- h. Changes to the above since previous assessment: see Section A.3. Changes to the assessment methodology.
- i. Outline of methods used to validate the code used to implement the model and whether the code is available: The code is available.

### **3. Model Selection and Evaluation**

- a. Alternative model configurations (scenarios):

**1.** The base scenario in September 2015. Scenario 1 includes:

- (1) Basic  $M = 0.18$ , with an additional mortality level during 1980-1984 for males and two additional mortality levels (one for 1980-1984 and the other for 1976-1979 and 1985-1993) for females.
- (2) Including BSFRF survey data in 2007 and 2008. The BSFRF survey is treated as an independent survey, and no assumption is made about the capture probabilities of the BSFRF survey. In effect, survey selectivities for both surveys are estimated separately and directly in the model.
- (3) NMFS survey catchability is estimated in the model and is assumed to be constant over time. BSFRF survey catchability is assumed to be 1.0.
- (4) Two levels of molting probabilities for males: one before 1980 and one after 1979, based on survey shell condition data. Each level has two parameters.
- (5) Estimating effective sample size from observed sample sizes. Effective sample sizes are estimated as  $\min(0.5*\text{observed-size}, N)$  for trawl surveys and  $\min(0.1*\text{observed-size}, N)$  for catch and bycatch, where  $N$  is the maximum sample size (200 for trawl surveys, 100 for males from the pot fishery and 50 for females from pot fishery and both males and females from the trawl fisheries. There is a justification for enforcing a maximum limit to effective sample sizes because the number of length measurements is large (Fournier et al. 1998). The effective sample sizes are plotted against the implied effective sample sizes in Figures 6 and 7, where the implied effective sample sizes are estimated as follows:

$$n_y = \sum_l \hat{P}_{y,l} (1 - \hat{P}_{y,l}) / \sum_l (P_{y,l} - \hat{P}_{y,l})^2 \quad (1)$$

2

where  $\hat{P}_{y,l}$  and  $P_{y,l}$  are estimated and observed size compositions in year  $y$  and length group  $l$ , respectively.

(6) Standard survey data for males and retow data for females.

(7) Estimating initial year length compositions.

**1n.** Same as scenario 1 plus additional BSFRF survey data in 2013-2016.

For scenarios 1 and 1n, survey abundances  $\hat{N}_{s,y,l}^b$  (BSFRF survey) and  $\hat{N}_{s,y,l}^n$  (NMFS survey) by sex  $s$  and in year  $y$  and length group  $l$  are computed as follows:

$$\begin{aligned}\hat{N}_{s,y,l}^b &= N_{s,y,l} s_{s,l}^b, \\ \hat{N}_{s,y,l}^n &= N_{s,y,l} s_{s,l}^n,\end{aligned}\tag{2}$$

where  $s_{s,l}^b$  and  $s_{s,l}^n$  are survey selectivities for BSFRF and NMFS surveys by sex  $s$  and in length group  $l$ , respectively, and  $N_{s,y,l}$  is the population abundance by sex  $s$  and in year  $y$  and length group  $l$ . The NMFS (1982-2016) and BSFRF survey selectivities are computed as

$$\begin{aligned}s_{s,l}^n &= \frac{Q}{1 + e^{-\beta_s^n (t - L_{50,s}^n)}}, \\ s_{s,l}^b &= \frac{1}{1 + e^{-\beta_s^b (t - L_{50,s}^b)}},\end{aligned}\tag{3}$$

where  $\beta$  and  $L_{50}$  are parameters and  $Q$  is the NMFS survey catchability. Survey selectivity for the first length group (67.5 mm) was assumed to be the same for both males and females, so only three parameters ( $\beta$ ,  $L_{50}$  for females and  $L_{50}$  for males) were estimated in the model for each survey.  $Q$  is estimated in the model with or without a prior from the double-bag experiment, depending on scenarios. The BSFRF survey catchability is assumed to be 1.0.

**2.** Same as scenario 1n except for making an assumption that the BSFRF survey capture probabilities are 1.0 for all length groups. Under this assumption, NMFS survey selectivities are the products of crab availabilities (equal to BSFRF survey selectivities) and NMFS survey capture probabilities ( $p$ ):

$$s_{s,l}^n = p_{s,l} s_{s,l}^b.\tag{4}$$

Therefore, the model estimates NMFS survey capture probabilities and BSFRF survey selectivities and computes NMFS survey selectivities from these estimates. NMFS survey capture probabilities are computed as

$$p_{s,l} = \frac{Q}{1 + e^{-\beta_s (l - L_{50,s})}}, \quad (5)$$

where  $\beta$  and  $L50$  are parameters and similar to the survey selectivities, only three parameters ( $\beta$ ,  $L50$  for females and  $L50$  for males) were estimated in the model for each sex.

- b. Progression of results: See the new results at the beginning of the report.
- c. Evidence of search for balance between realistic and simpler models: NA.
- d. Convergence status/criteria: ADMB default convergence criteria.
- e. Sample sizes for length composition data: observed sample sizes are summarized in Table 2, and estimated implied sample sizes and effective sample sizes are illustrated in Figures 6 and 7.
- f. Credible parameter estimates: All estimated parameters seem to be credible.
- g. Model selection criteria: The likelihood values were used to select among alternatives that could be legitimately compared by that criterion.
- h. Residual analysis: Residual plots are illustrated in figures.
- i. Model evaluation is provided under Results, below.
- j. Jittering: the Stock Synthesis Approach is used to do jittering to find the optimum:

The *Jitter* factor of 0.1 is multiplied by a random normal deviation  $rdev=N(0,1)$ , to a transformed parameter value based upon the predefined parameter:

$$\text{temp} = 0.5 rdev \text{ Jitter} \ln\left(\frac{P_{\max} - P_{\min} + 0.0000002}{P_{\text{val}} - P_{\min} + 0.0000001} - 1\right), \quad (6)$$

with the final jittered starting parameter value backtransformed as:

$$P_{\text{new}} = P_{\min} + \frac{P_{\max} - P_{\min}}{1.0 + \exp(-2.0 \text{ temp})}, \quad (7)$$

where  $P_{\max}$  and  $P_{\min}$  are upper and lower bounds of parameters and  $P_{\text{val}}$  is the estimated parameter value before the jittering. The jittering results are summarized in Table 3 for three scenarios. Most runs converge to the highest log likelihood values.

## 4. Results

- a. Effective sample sizes and weighting factors.

i. The effective sample sizes are:

- (1) Trawl surveys: 200 for males and females except for females: 184 in 1986, 180 in 1992, and 133 in 1994, and except for males 187 in 2016.
- (2) Retained catch: 100.
- (3) Pot male discard: 100 except 87 in 1990 and 23 in 1996.
- (4) Pot female discard: 50 except 38 in 1991, 1 in 1996, 4 in 1999, and 30 in 2002.
- (5) Trawl bycatch: 50 for males and females except for males 44 in 1988, 21 in 1991 and 1992, 33 in 1994, 10 in 1995, and for females 28 in 1986 and 1988, 19 in 1989, 40 in 1991, 11 in 1992, 25 in 1994, 5 in 1995, 48 in 1997.
- (6) Tanner fishery bycatch: 50 for males and females except for males 28 in 1992, 23 in 1993, 22 in 2013, and 26 in 2014, and for females 27 in 1993 and 38 in 2014.
- (7) BSFRF survey:

Year:	2007	2008	2013	2014	2015	2016
Females:	200	200	56	103	92	116
Males:	200	200	95	109	106	56

For scenario 1, effective sample sizes are illustrated in Figures 6 and 7.

ii. Weights are assumed to be 500 for retained catch biomass, and 100 for all bycatch biomasses, 2 for recruitment variation, and 10 for recruitment sex ratio.

iii. Initial trawl survey catchability ( $Q$ ) is estimated to be 0.896 with a standard deviation of 0.025 (CV about 0.03) based on the double-bag experiment results. These values are used as a prior for estimating  $Q$  in the model.

b. Tables of estimates.

- i. Parameter estimates for scenarios 1, 1n and 2 are summarized in Tables 4 and 5.
- ii. Abundance and biomass time series are provided in Table 6 for scenarios 1, 1n and 2.
- iii. Recruitment time series for scenarios 1, 1n and 2 are provided in Table 6.
- iv. Time series of catch biomass is provided in Table 1.

Negative log-likelihood values and parameter estimates are summarized in Tables 4 and 5, respectively. Length-specific fishing mortality is equal to selectivity-at-length times the full fishing mortality. Estimated full pot fishing mortalities for females and full fishing mortalities for trawl bycatch were very low due to low bycatch as well as handling mortality rates less than 1.0. Estimated recruits varied greatly from year to year (Table 6). Estimated low selectivities for male pot bycatch, relative to the retained catch, reflected the 20% handling mortality rate (Figure 8). Both selectivities were applied to the same level of full fishing mortality. Estimated selectivities for female pot bycatch were close to 1.0 for all mature females, and the estimated full fishing mortalities for female pot bycatch were lower than for male retained catch and bycatch (Table 5).

c. Graphs of estimates.

- i. Selectivities and molting probabilities by length are provided in Figures 8 and 9 for scenarios 1, 1n and 2.

One of the most important results is estimated trawl survey selectivity (Figure 8). Survey selectivity affects not only the fitting of the data but also the absolute abundance estimates. Estimated survey selectivities in Figure 8 are generally smaller than the capture probabilities in Figure A1 because survey selectivities include capture probabilities and crab availability. The NMFS survey catchability was estimated to be 0.896 from the trawl experiment, which is higher than that estimated from the BSFRF surveys (0.854). The reliability of estimated survey selectivities will greatly affect the application of the model to fisheries management. Under- or overestimates of survey selectivities will cause a systematic upward or downward bias of abundance estimates. Information about crab availability to the survey area at survey times will help estimate the survey selectivities.

For scenarios 1 and 1n, estimated molting probabilities during 1975-2016 (Figure 9) were generally lower than those estimated from the 1954-1961 and 1966-1969 tagging data (Balsiger 1974). Lower molting probabilities mean more oldshell crab, possibly due to changes in molting probabilities over time or shell aging errors. Overestimates or underestimates of oldshell crab will result in lower or higher estimates of male molting probabilities.

- ii. Estimated total survey biomass and mature male and female abundances are plotted in Figure 10. Absolute mature male biomasses are illustrated in Figure 11.

Model estimated relative survey biomasses are very similar among the three scenarios and fit the survey data quite well. The absolute population biomass estimates are slightly higher for scenario 2 than for scenarios 1 and 1n during recent years due to a slightly lower estimate of trawl survey selectivities for scenario 2 and additional BSFRF survey data for scenarios 1n and 2.

Although the model did not fit the mature crab abundances directly, trends in the mature abundance estimates agree well with observed survey values except in 2014 (Figure 10b). Estimated mature crab abundance increased dramatically in the mid 1970s then decreased precipitously in the early 1980s. Estimated mature crab abundance had increased during 1985-2009 with mature females being about 3 times more abundant in 2009 than in 1985 and mature males being about 2 times more abundant in 2009 than in 1985. Estimated mature abundance has declined since 2009 (Figure 10b). Model estimates of both male and female mature abundances have steadily declined since the late 2000s. Absolute mature male biomasses for scenarios 1, 1n and 2 have a similar trend over time (Figure 11).

The fit to BSFRF survey data and estimated survey selectivities are illustrated in Figures 10c-e.

- iii. Estimated recruitment time series are plotted in Figure 12 for scenarios 1, 1n and 2.

- iv. Estimated fishing mortality rates are plotted against mature male biomass in Figure 13 for scenarios 1, 1n and 2.

The average of estimated male recruits from 1984 to 2016 (Figure 12) and mature male biomass per recruit were used to estimate  $B_{35\%}$ . Alternative periods of 1976-present and 1976-1983 were compared in our report. The full fishing mortalities for the directed pot fishery at the time of fishing were plotted against mature male biomass on Feb. 15 (Figure 13). Estimated fishing mortalities in most years before the current harvest strategy was adopted in 1996 were above  $F_{35\%}$  (Figure 13). Under the current harvest strategy, estimated fishing mortalities were at or above the  $F_{35\%}$  limits in 1998, 2005, 2007-2009 for three scenarios but below the  $F_{35\%}$  limits in the other post-1995 years. The estimated higher survey selectivities with scenarios 1 and 1n result in relatively higher fishing mortalities than those with scenario 2.

For scenario 1, estimated full pot fishing mortalities ranged from 0.00 to 1.56 during 1975-2015, with estimated values over 0.40 during 1975-1981, 1986-1987 and 2008 (Table 5, Figure 13). For scenario 1n, estimated full pot fishing mortalities ranged from 0.00 to 1.56 during 1975-2015, with estimated values over 0.40 during 1975-1981, 1986-1987 and 2008 (Figure 13). Estimated fishing mortalities for pot female and trawl bycatches were generally less than 0.06.

- v. Estimated mature male biomass and recruitment are plotted to illustrate their relationships with scenario 1 (Figure 14a). Annual stock productivities are illustrated in Figure 14b.

Stock productivity (recruitment/mature male biomass) was generally lower during the last 20 years (Figure 14c).

Egg clutch data collected during summer surveys may provide information about mature female reproductive conditions. Although egg clutch data are subject to rating errors as well as sampling errors, data trends over time may be useful. Proportions of empty clutches for newshell mature females >89 mm CL were high in some years before 1990, but have been low since 1990 (Figure 15). The highest proportion of empty clutches (0.2) was in 1986, and primarily involved soft shell females (shell condition 1). Clutch fullness fluctuated annually around average levels during two periods: before 1991 and after 1990 (Figure 15). The average clutch fullness was similar for these two periods (Figure 15).

d. Graphic evaluation of the fit to the data.

- i. Observed vs. estimated catches are plotted in Figure 16.
- ii. Model fits to total survey biomass are shown in Figure 10 with a standardized residual plot in Figure 17.
- iii. Model fits to catch and survey proportions by length are illustrated in Figures 18-24 and residual bubble plots are shown in Figures 25-26.

The model (three scenarios) fit the fishery biomass data well and the survey biomass reasonably well (Figures 10 and 16). Because the model estimates annual fishing

mortality for directed pot male catch, undirected pot male bycatch, pot female bycatch, and trawl bycatch, the deviations of observed and predicted (estimated) fishery biomass are mainly due to size composition differences.

The model also fit the length composition data well (Figures 18-24). The model also fit the length proportions of the pot male bycatch well with two simple linear selectivity functions (Figure 21). We explored a logistic selectivity function, but due to the long left tail of the pot male bycatch selectivity, the logistic selectivity function did not fit the data well.

Modal progressions are tracked well in the trawl survey data, particularly beginning in the mid-1990s (Figures 18 and 19). Cohorts first seen in the trawl survey data in 1975, 1986, 1990, 1995, 1999, 2002 and 2005 can be tracked over time. Some cohorts can be tracked over time in the pot bycatch as well (Figure 21), but the bycatch data did not track the cohorts as well as the survey data. Groundfish trawl bycatch data provide little information to track modal progression (Figures 23 and 24).

Standardized residuals of total survey biomass and proportions of length are plotted to examine their patterns. Residuals were calculated as observed minus predicted and standardized by the estimated standard deviation. Standardized residuals of total survey biomass did not show any consistent patterns (Figure 17). Standardized residuals of proportions of survey males appear to be random over length and year (Figure 25). There is an interesting pattern for residuals of proportions of survey females. Residuals were generally negative for large-sized mature females during 1975-1987 for scenarios 1 and 1n (Figure 26). Changes in growth over time or increased mortality may cause this pattern. The inadequacy of the model can be corrected by adding parameters to address these factors or with improved growth data.

e. Retrospective and historic analyses.

Two kinds of retrospective analyses were conducted for this report: (1) the 2016 model (scenario 1) hindcast results and (2) historical results. The 2016 model results are based on sequentially excluding one-year of data to evaluate the current model performance with fewer data. The historical results are the trajectories of biomass and abundance from previous assessments that capture both new data and changes in methodology over time. Treating the 2016 estimates as the baseline values, we can also evaluate how well the model had done in the past.

i. Retrospective analysis (retrospective bias in base model or models).

The performance of the 2016 model includes sequentially excluding one-year of data. The model with scenario 1 performed reasonably well during 2008-2015 with a lower terminal year estimates in 2012 and 2013 and higher estimates during 2008-2010 (Figures 27-28).

ii. Historic analysis (plot of actual estimates from current and previous assessments).

The model first fit the data from 1985 to 2004 in the terminal year of 2004. Thus, sequentially incrementing the terminal year provided 10 historical assessments for comparison with the 2016 assessment model results (Figure 29). The main

differences of the 2004 model were weighting factors and effective sample sizes for the likelihood functions. In 2004, the weighting factors were 1,000 for survey biomass, 2,000 for retained catch biomass and 200 for bycatch biomasses. The effective sample sizes were set to be 200 for all proportion data but weighting factors of 5, 2, and 1 were also respectively applied to retained catch proportions, survey proportions and bycatch proportions. Estimates of time series of abundance in 2004 were generally higher than those estimated after 2004 (Figure 29).

In 2005, to improve the fit for retained catch data, the weight for retained catch biomass was increased to 3,000 and the weight for retained catch proportions was increased to 6. All other weights were not changed. In 2006, all weights were re-configured. No weights were used for proportion data, and instead, effective sample sizes were set to 500 for retained catch, 200 for survey data, and 100 for bycatch data. Weights for biomasses were changed to 800 for retained catch, 300 for survey and 50 for bycatch. The weights in 2007 were the same as 2006. Generally, estimates of time series of abundance in 2005 were slightly lower than in 2006 and 2007, and there were few differences between estimates in 2006 and 2007 (Figure 29).

In 2008, estimated coefficients of variation for survey biomass were used to compute likelihood values as suggested by the CPT in 2007. Thus, weights were re-configured to: 500 for retained catch biomass, 50 for survey biomass, and 20 for bycatch biomasses. Effective sample size was lowered to 400 for the retained catch data. These changes were necessary for the estimation to converge and for a relatively good balanced fit to both biomasses and proportion data. Also, sizes at 50% selectivities for all fisheries data were allowed to change annually, subject to a random walk pattern, for all assessments before 2008. The 2008 model does not allow annual changes in any fishery selectivities. Except for higher estimates of abundance during the late 1980s and early 1990s, estimates of time series of abundance in 2008 were generally close to those in 2006 and 2007 (Figure 29).

During 2009-2013, the model was extended to the data through 1968. No weight factors were used for the NMFS survey biomass during 2009-2013 assessments. Since 2013, the model has fitted the data only back to 1975 for consistence of trawl survey data. Two levels of molting probabilities over time were used, shell conditions for males were combined, and length composition data of the BSFRF survey were used as well. In 2014 and 2015, the trawl survey time series were re-estimated and a trawl survey catchability was estimated for some scenarios.

Overall, both historical results (historic analysis) and the 2016 model results (retrospective analysis) performed reasonably well. No great overestimates or underestimates occurred as was observed in assessments for Pacific halibut (*Hippoglossus stenolepis*) (Parma 1993) and some eastern Bering Sea groundfish stocks (Zheng and Kruse 2002; Ianelli et al. 2003). Since the most recent model was not used to set TAC or overfishing limits until 2009, historical implications for management from the stock assessment errors cannot be evaluated at the current time. However,

management implications of the ADF&G stock assessment model were evaluated by Zheng and Kruse (2002).

f. Uncertainty and sensitivity analyses

- i. Estimated standard deviations of parameters are summarized in Table 5 for scenarios 1, 1n and 2. Estimated standard deviations of mature male biomass are listed in Table 6.
- ii. Probabilities for trawl survey catchability  $Q$  are illustrated in Figure 30 for scenarios 1, 1n and 2 using the mcmc approach; estimated  $Q$ s are generally less than 1.0. Probabilities for mature male biomass and OFL in 2016 are illustrated in Figure 31 for scenarios 1, 1n and 2 using the mcmc approach. The confidence intervals are quite narrow.
- iii. Sensitivity analysis for handling mortality rate was reported in the SAFE report in May 2010. The baseline handling mortality rate for the directed pot fishery was set at 0.2. A 50% reduction and 100% increase respectively resulted in 0.1 and 0.4 as alternatives. Overall, a higher handling mortality rate resulted in slightly higher estimates of mature abundance, and a lower rate resulted in a minor reduction of estimated mature abundance. Differences of estimated legal abundance and mature male biomass were small among these handling mortality rates.
- iv. Sensitivity of weights. Sensitivity of weights was examined in the SAFE report in May 2010. Weights to biomasses (trawl survey biomass, retained catch biomass, and bycatch biomasses) were reduced to 50% or increased to 200% to examine their sensitivity to abundance estimates. Weights to the penalty terms (recruitment variation and sex ratio) were also reduced or increased. Overall, estimated biomasses were very close under different weights except during the mid-1970s. The variation of estimated biomasses in the mid-1970s was mainly caused by the changes in estimates of additional mortalities in the early 1980s.

g. Comparison of alternative model scenarios

These comparisons, based on the data through 2010, were reported in the SAFE report in May 2011. Estimating length proportions in the initial year (scenario 1a) results in a better fit of survey length compositions at an expense of 36 more parameters than scenario 1. Abundance and biomass estimates with scenario 1a are similar between scenarios. Using only standard survey data (scenario 1b) results in a poorer fit of survey length compositions and biomass than scenarios using both standard and re-tow data (scenarios 1, 1a, and 1c) and has the lowest likelihood value. Although the likelihood value is higher for using both standard survey and re-tow data for males (scenario 1) than using only standard survey for males (scenario 1c), estimated abundances and biomasses are almost identical. The higher likelihood value for scenario 1 over scenario 1c is due to trawl bycatch length compositions.

In this report (September 2016), three scenarios are compared. Model estimated relative survey biomasses are very similar among the scenarios. The absolute population biomass estimates are slightly higher for scenarios 1n and 2 than for scenario 1 during recent years

due to additional BSFRF survey data during 2013-2016. A slightly lower estimate of NMFS trawl survey selectivities for scenario 2 also results in slightly higher absolute biomass during recent years for scenario 2 than for scenario 1n. Overall, the results for all three scenarios are similar.

## ***F. Calculation of the OFL and ABC***

1. Bristol Bay RKC is currently placed in Tier 3b (NPFMC 2007).
2. For Tier 3 stocks, estimated biological reference points include  $B_{35\%}$  and  $F_{35\%}$ . Estimated model parameters were used to conduct mature male biomass-per-recruit analysis.
3. Specification of the OFL:

The Tier 3 can be expressed by the following control rule:

$$\begin{aligned}
 \text{a)} \quad & \frac{B}{B^*} > 1 & F_{OFL} &= F^* \\
 \text{b)} \quad & \beta < \frac{B}{B^*} \leq 1 & F_{OFL} &= F^* \left( \frac{B / B^* - \alpha}{1 - \alpha} \right) \\
 \text{c)} \quad & \frac{B}{B^*} \leq \beta & \text{directed fishery } F = 0 \text{ and } F_{OFL} \leq F^*
 \end{aligned} \tag{1}$$

Where

$B$  = a measure of the productive capacity of the stock such as spawning biomass or fertilized egg production. A proxy of  $B$ , MMB estimated at the time of primiparous female mating (February 15) is used as a default in the development of the control rule.

$F^* = F_{35\%}$ , a proxy of  $F_{MSY}$ , which is a full selection instantaneous  $F$  that will produce MSY at the MSY producing biomass,

$B^* = B_{35\%}$ , a proxy of  $B_{MSY}$ , which is the value of biomass at the MSY producing level,

$\beta$  = a parameter with restriction that  $0 \leq \beta < 1$ . A default value of 0.25 is used.

$\alpha$  = a parameter with restriction that  $0 \leq \alpha \leq \beta$ . A default value of 0.1 is used.

Because trawl bycatch fishing mortality was not related to pot fishing mortality, average trawl bycatch fishing mortality during 2006 to 2015 was used for the per recruit analysis as well as for projections in the next section. Pot female bycatch fishing mortality was set equal to pot male fishing mortality times 0.02, an intermediate level during 1990-2015. Some discards of legal males occurred since the IFQ fishery started in 2005, but the discard rates were much lower during 2007-2013 than in 2005 after the fishing industry minimized discards of legal males. However, due to the high proportion of large oldshell males, the discard rate increased greatly in 2014. The average of retained selectivities and discard male selectivities during 2013-2015 were used to represent current trends for per recruit analysis

and projections. Average molting probabilities during 2006-2015 were used for per recruit analysis and projections.

Average recruitments during three periods were used to estimate  $B_{35\%}$ : 1976-1983, 1976-2016, and 1984-2016 (Figure 12). Estimated  $B_{35\%}$  is compared with historical mature male biomass in Figure 13a. We recommend using the average recruitment during 1984-present, corresponding to the 1976/77 regime shift. Note that recruitment period 1984-present has been used since 2011 to set the overfishing limits. Several factors support our recommendation. First, estimated recruitment was lower after 1983 than before 1984, which corresponded to brood years 1978 and later, after the 1976/77 regime shift. Second, high recruitments during the late 1960s and 1970s generally occurred when the spawning stock was primarily located in the southern Bristol Bay, whereas the current spawning stock is mainly in the middle of Bristol Bay. The current flows favor larvae hatched in the southern Bristol Bay (see the section on Ecosystem Considerations for SAFE reports in 2008 and 2009). Finally, stock productivity (recruitment/mature male biomass) was higher before the 1976/1977 regime shift.

If we believe that differences in productivity and other population characteristics before 1978 were caused by fishing, not by the regime shift, then we should use the recruitment from 1976-1983 (corresponding to brood years before 1978) as the baseline to estimate  $B_{35\%}$ . If we believe that the regime shift during 1976/77 caused the productivity differences, then we should select the recruitments from period 1984-2016 as the baseline.

The control rule is used for stock status determination. If total catch exceeds OFL estimated at  $B$ , then “overfishing” occurs. If  $B$  equals or declines below 0.5  $B_{MSY}$  (i.e., MSST), the stock is “overfished.” If  $B$  equals or declines below  $\beta^*B_{MSY}$  or  $\beta^*$ a proxy  $B_{MSY}$ , then the stock productivity is severely depleted and the fishery is closed.

The estimated probability distribution of MMB in 2016 is illustrated in Figure 30. Based the SSC suggestion in 2011, ABC = 0.9\*OFL is used to estimate ABC.

Status and catch specifications (1,000 t) (scenario 2):

<b>Year</b>	<b>MSST</b>	<b>Biomass (MMB)</b>	<b>TAC</b>	<b>Retained Catch</b>	<b>Total Catch</b>	<b>OFL</b>	<b>ABC</b>
2012/13	13.19 <sup>A</sup>	29.05 <sup>A</sup>	3.56	3.62	3.90	7.96	7.17
2013/14	12.85 <sup>B</sup>	27.12 <sup>B</sup>	3.90	3.99	4.56	7.07	6.36
2014/15	13.03 <sup>C</sup>	27.25 <sup>C</sup>	4.49	4.54	5.44	6.82	6.14
2015/16	12.89 <sup>D</sup>	27.68 <sup>D</sup>	4.52	4.61	5.34	6.73	6.06
2016/17		24.00 <sup>D</sup>				6.64	5.97

The stock was above MSST in 2015/16 and is hence not overfished. Overfishing did not occur.

Status and catch specifications (million lbs):

<b>Year</b>	<b>MSST</b>	<b>Biomass (MMB)</b>	<b>TAC</b>	<b>Retained Catch</b>	<b>Total Catch</b>	<b>OFL</b>	<b>ABC</b>
2012/13	29.1 <sup>A</sup>	64.0 <sup>A</sup>	7.85	7.98	8.59	17.55	15.80
2013/14	28.3 <sup>B</sup>	59.9 <sup>B</sup>	8.60	8.80	10.05	15.58	14.02
2014/15	28.7 <sup>C</sup>	60.1 <sup>C</sup>	9.99	10.01	11.99	15.04	13.53
2015/16	28.4 <sup>D</sup>	61.0 <sup>D</sup>	9.97	10.17	11.77	14.84	13.36
2016/17		52.9 <sup>D</sup>				14.63	13.17

Notes:

A – Calculated from the assessment reviewed by the Crab Plan Team in September 2013

B – Calculated from the assessment reviewed by the Crab Plan Team in September 2014

C – Calculated from the assessment reviewed by the Crab Plan Team in September 2015

D – Calculated from the assessment reviewed by the Crab Plan Team in September 2016

4. Based on the  $B_{35\%}$  estimated from the average male recruitment during 1984-2016, the biological reference points and OFL were estimated as follows:

	Scenario 1		Scenario 1n		Scenario 2	
$B_{35\%}$	1,000t	Mill. lbs	1,000t	Mill. lbs	1,000t	Mill. lbs
	24.777	54.624	24.907	54.910	25.785	56.846
$F_{35\%}$	0.29		0.29		0.29	
$MMB_{2016}$	22.381	49.341	23.014	50.736	23.999	52.908
$OFL_{2016}$	6.040	13.316	6.385	14.076	6.637	14.633
$ABC_{2016}$	5.436	11.984	5.746	12.668	5.937	13.169

5. Based on the 10% buffer rule used last year,  $ABC = 0.9 * OFL$ . If  $P^* = 49\%$  is used, the ABC will be higher.

## G. Rebuilding Analyses

NA.

## H. Data Gaps and Research Priorities

1. The following data gaps exist for this stock:
  - a. Information about changes in natural mortality in the early 1980s;
  - b. Un-observed trawl bycatch in the early 1980s;
  - c. Natural mortality;
  - d. Crab availability to the trawl surveys;
  - e. Juvenile crab abundance;
  - f. Female growth per molt as a function of size and maturity;
  - g. Changes in male molting probability over time.

2. Research priorities:
  - a. Estimating natural mortality;
  - b. Estimating crab availability to the trawl surveys;
  - c. Surveying juvenile crab abundance in nearshore;
  - d. Studying environmental factors that affect the survival rates from larvae to recruitment.

## ***I. Projections and Future Outlook***

### **1. Projections**

Future population projections primarily depend on future recruitment, but crab recruitment is difficult to predict. Therefore, annual recruitment for the projections was a random selection from estimated recruitments during 1984-2016. Besides recruitment, the other major uncertainty for the projections is estimated abundance in 2016. The 2016 abundance was randomly selected from the estimated normal distribution of the assessment model output for each replicate. Three scenarios of fishing mortality for the directed pot fishery were used in the projections:

- (1) No directed fishery. This was used as a base projection.
- (2)  $F_{40\%}$ . This fishing mortality creates a buffer between the limits and target levels.
- (3)  $F_{35\%}$ . This is the maximum fishing mortality allowed under the current overfishing definitions.

Each scenario was replicated 1,000 times and projections made over 10 years beginning in 2016 (Table 7).

As expected, projected mature male biomasses are much higher without the directed fishing mortality than under the other scenarios. At the end of 10 years, projected mature male biomass is above  $B_{35\%}$  for all scenarios (Table 7; Figure 32). Projected retained catch for the  $F_{35\%}$  scenario is higher than those for the  $F_{40\%}$  scenario (Table 7, Figure 33). Due to the poor recruitment in recent years, the projected biomass and retained catch are expected to decline during the next few years.

### **2. Near Future Outlook**

The near future outlook for the Bristol Bay RKC stock is a declining trend. The three recent above-average year classes (hatching years 1990, 1994, and 1997) had entered the legal population by 2006 (Figure 34). Most individuals from the 1997 year class will continue to gain weight to offset loss of the legal biomass to fishing and natural mortalities. The above-average year class (hatching year 2000) with lengths centered around 87.5 mm CL for both males and females in 2006 and with lengths centered around 112.5-117.5 mm CL for males and around 107.5 mm CL for females in 2008 has largely entered the mature male population in 2009 and the legal population by 2014 (Figure 34). No strong cohorts have been observed in the survey data after this cohort through 2010 (Figure 34). There was a huge tow of juvenile crab of size 45-55 mm in 2011, but these juveniles were not observed during 2012-2016 surveys. This single tow is unlikely to be an indicator for a

strong cohort. The high survey abundance of large males and mature females in 2014 cannot be explained by the survey data during the previous years and were not followed with the 2015-2016 survey results (Figure 34). Due to lack of recruitment, mature and legal crab should continue to decline next year. Current crab abundance is still low relative to the late 1970s, and without favorable environmental conditions, recovery to the high levels of the late 1970s is unlikely.

### ***J. Acknowledgements***

Table 1a. Bristol Bay red king crab annual catch and bycatch mortality biomass (t) from June 1 to May 31. A handling mortality rate of 20% for the directed pot, 25% for the Tanner fishery, and 80% for trawl was assumed to estimate bycatch mortality biomass.

Year	Retained Catch			Pot Bycatch		Trawl Bycatch	Tanner Fishery Bycatch	Total Catch
	U.S.	Cost- Recovery	Foreign	Total	Males			
1953	1331.3		4705.6	6036.9				6036.9

Table 4a. Number of parameters and the list of likelihood components for the model (Scenarios 1, 1n and 2).

Parameter counts	Scenarios 1, 1n and 2
Fixed growth parameters	9
Fixed recruitment parameters	2
Fixed length-weight relationship parameters	6
Fixed mortality parameters	4
Fixed survey catchability parameter	1
Fixed high grading parameters	11
Total number of fixed parameters	33
Free survey catchability parameter	1
Free growth parameters	6
Initial abundance (1975)	1
Recruitment-distribution parameters	2
Mean recruitment parameters	1
Male recruitment deviations	41
Female recruitment deviations	41
Natural and fishing mortality parameters	4
Pot male fishing mortality deviations	43
Bycatch mortality from the Tanner crab fishery	11
Pot female bycatch fishing mortality deviations	28
Trawl bycatch fishing mortality deviations	42
Initial (1975) length compositions	35
BSFRF survey extra CV	1
Free selectivity parameters	22
Total number of free parameters	279
Total number of fixed and free parameters	312

#### **Negative log likelihood components (see table 4b)**

Length compositions---retained catch  
 Length compositions---pot male discard  
 Length compositions---pot female discard  
 Length compositions---survey  
 Length compositions---trawl discard  
 Length compositions---Tanner crab discards  
 Pot discard male biomass  
 Retained catch biomass  
 Pot discard female biomass  
 Trawl discard  
 Survey biomass  
 Recruitment variation  
 Total

Table 4b. Negative log likelihood components for scenarios 1, 1n, and 2 and differences in negative log-likelihood components among model scenarios.

Table 6(1). Annual abundance estimates (millions of crab), mature male biomass (MMB, 1000 t), and total survey biomass (1000 t) for red king crab in Bristol Bay estimated by length-based analysis (scenario 1) from 1975-2016. Mature male biomass for year  $t$  is on Feb. 15 of year  $t+1$ . Size measurements are mm carapace length.

Year (t)	Males			Females		Total Recruits	Trawl Survey Biomass

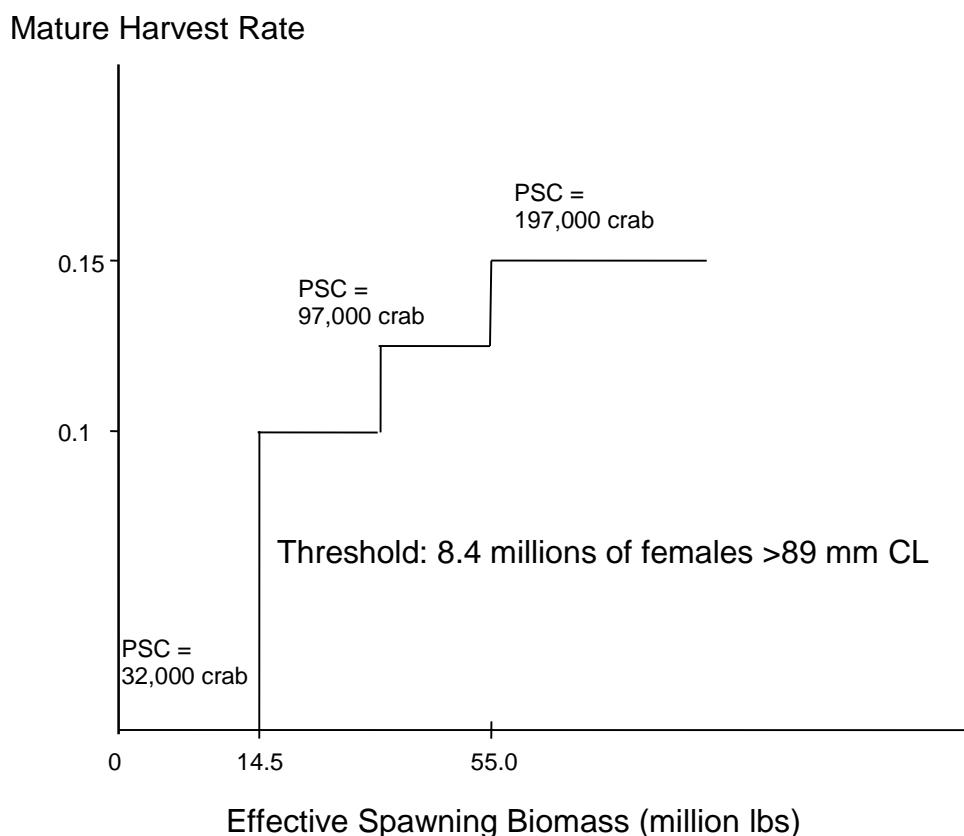

Figure 1. Current harvest rate strategy (line) for the Bristol Bay red king crab fishery and annual prohibited species catch (PSC) limits (numbers of crab) of Bristol Bay red king crab in the groundfish fisheries in zone 1 in the eastern Bering Sea. Harvest rates are based on current-year estimates of effective spawning biomass (ESB), whereas PSC limits apply to previous-year ESB.

## Data by type and year

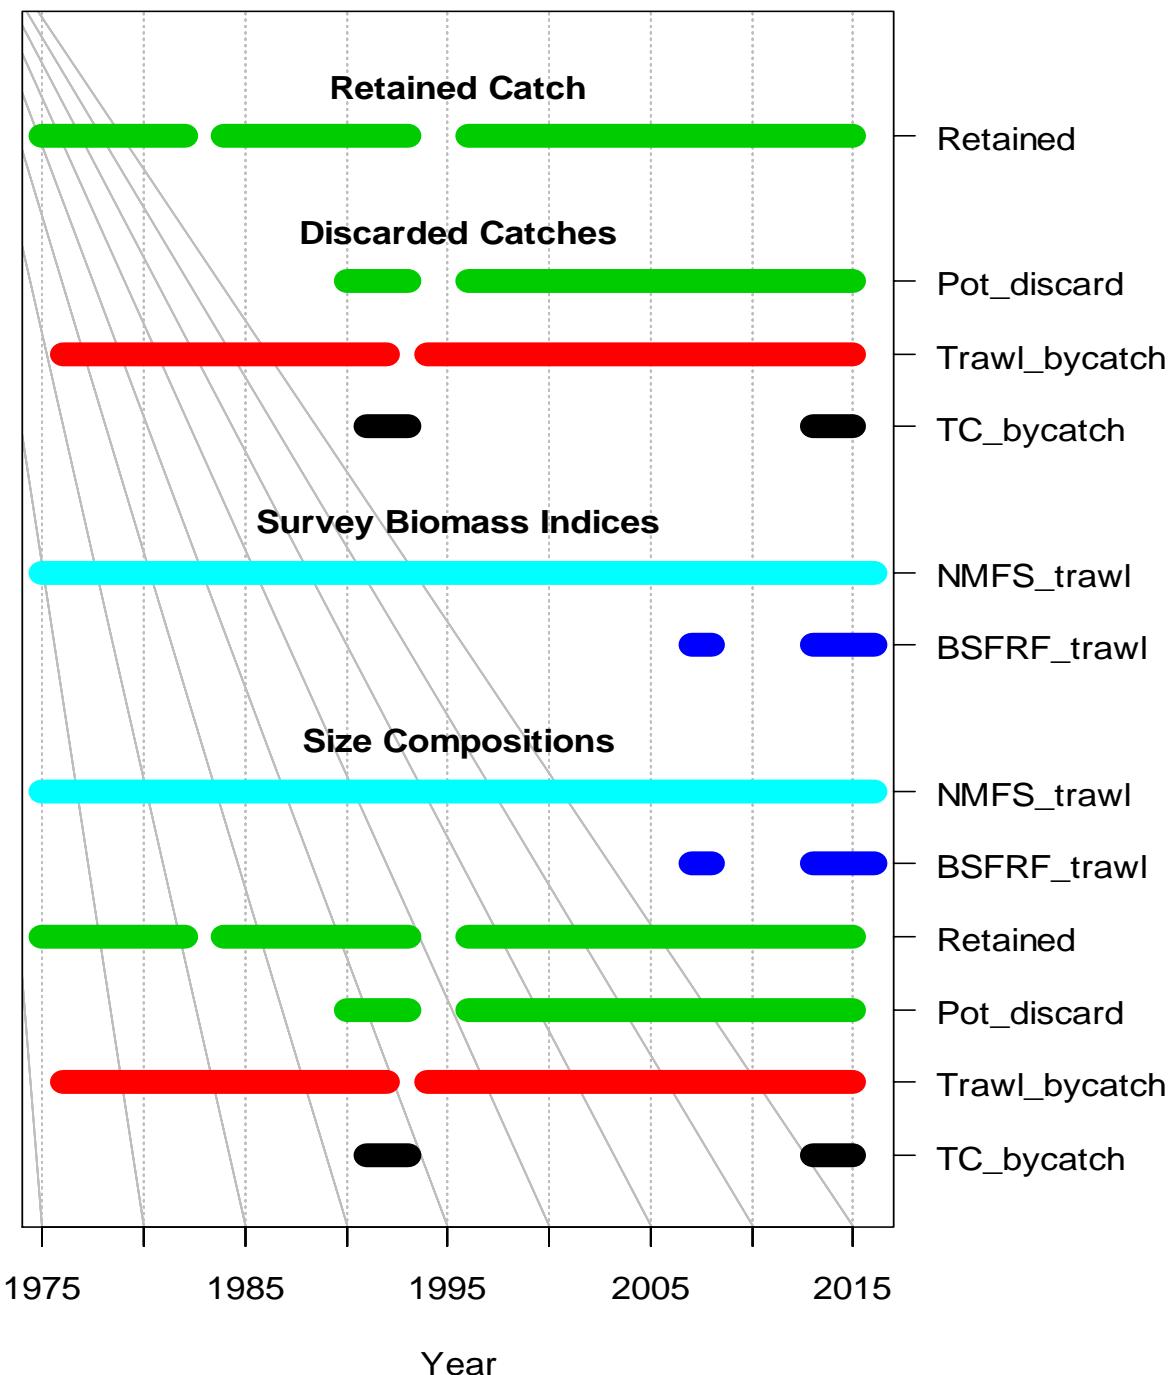

Figure 2. Data types and ranges used for the stock assessment.

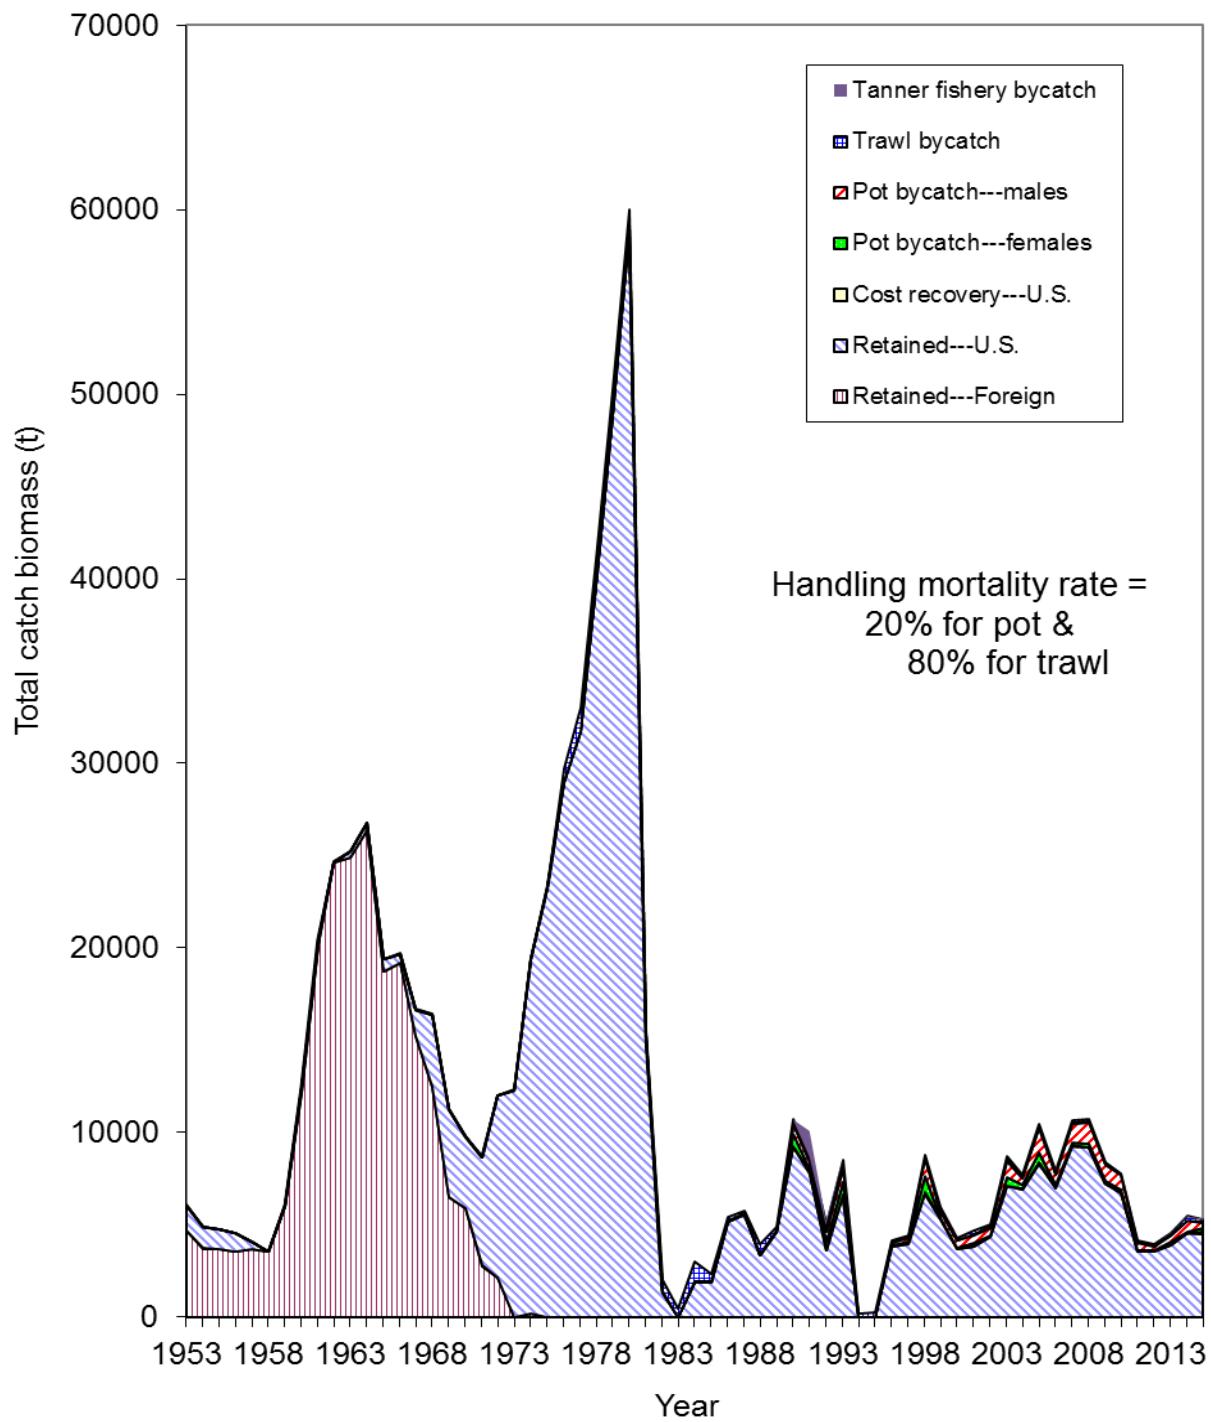

Figure 3. Retained catch biomass and bycatch mortality biomass (t) for Bristol Bay red king crab from 1953 to 2015. Handling mortality rates were assumed to be 0.2 for the directed pot fishery 0.25 for the Tanner crab fishery and 0.8 for the trawl fisheries.

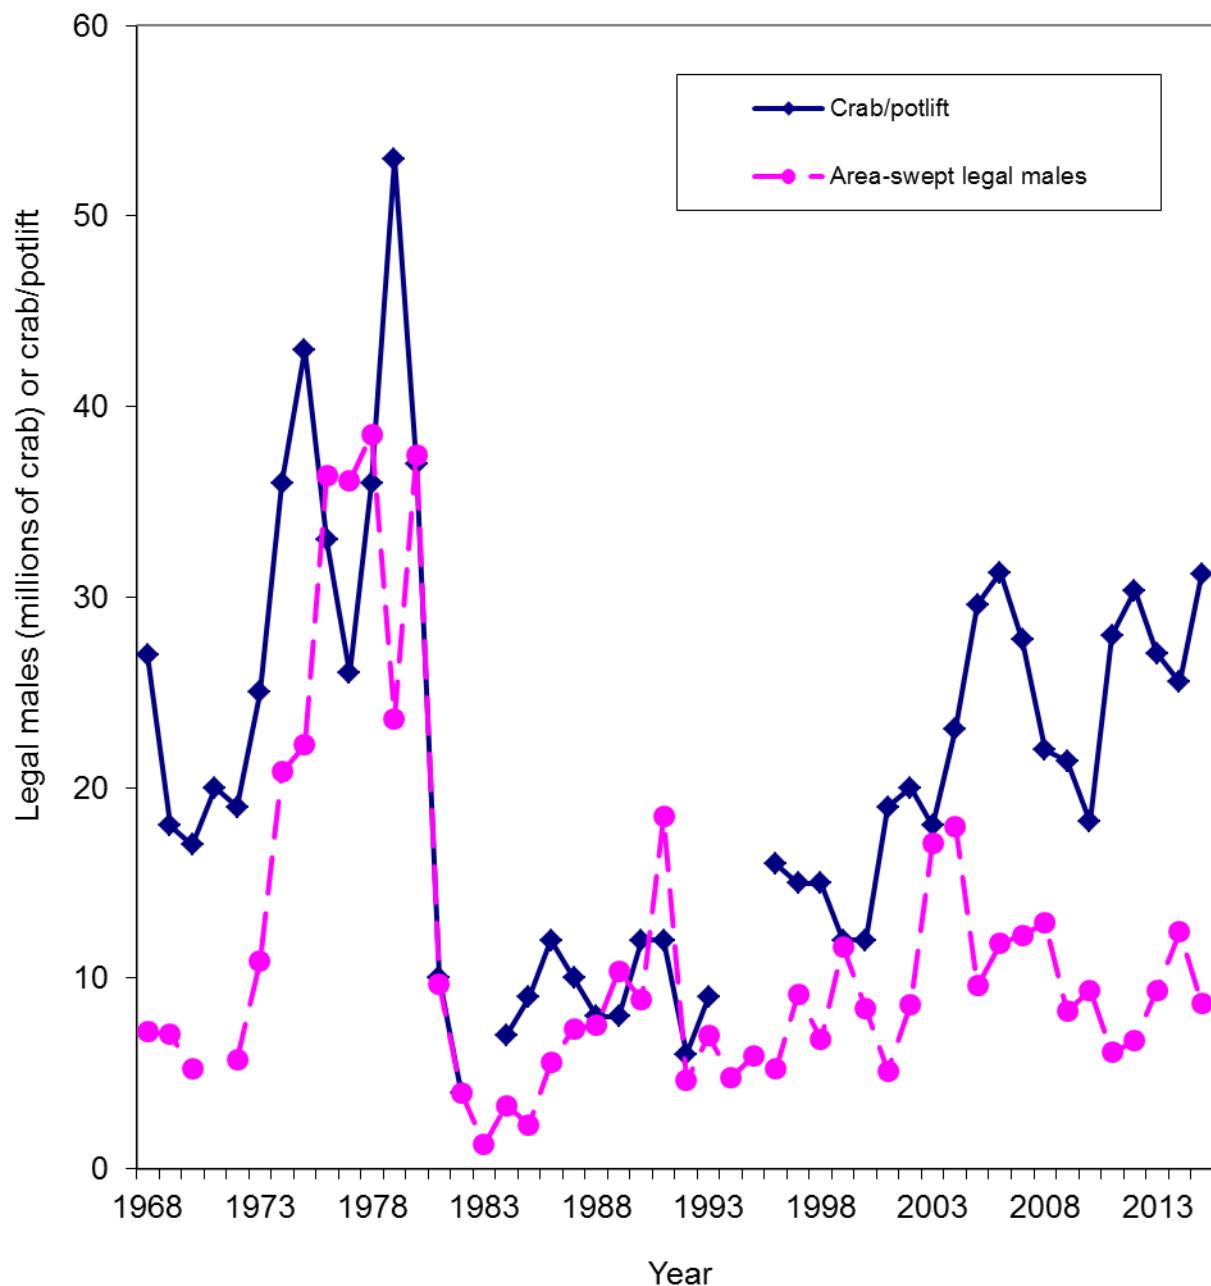

Figure 4. Comparison of survey legal male abundances and catches per unit effort for Bristol Bay red king crab from 1968 to 2015.

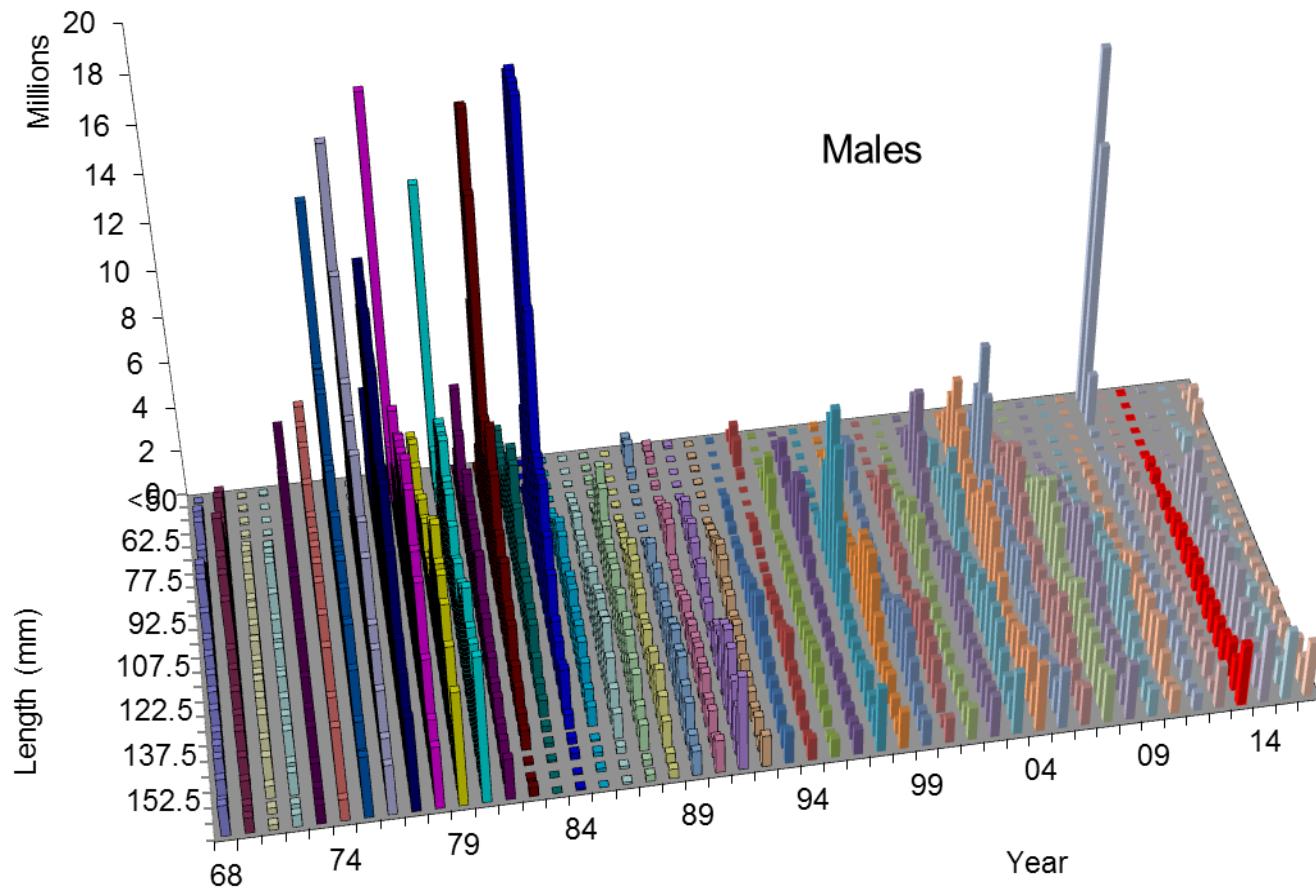

Figure 5a. Survey abundances by 5-mm carapace length bin for male Bristol Bay red king crab from 1968 to 2016.

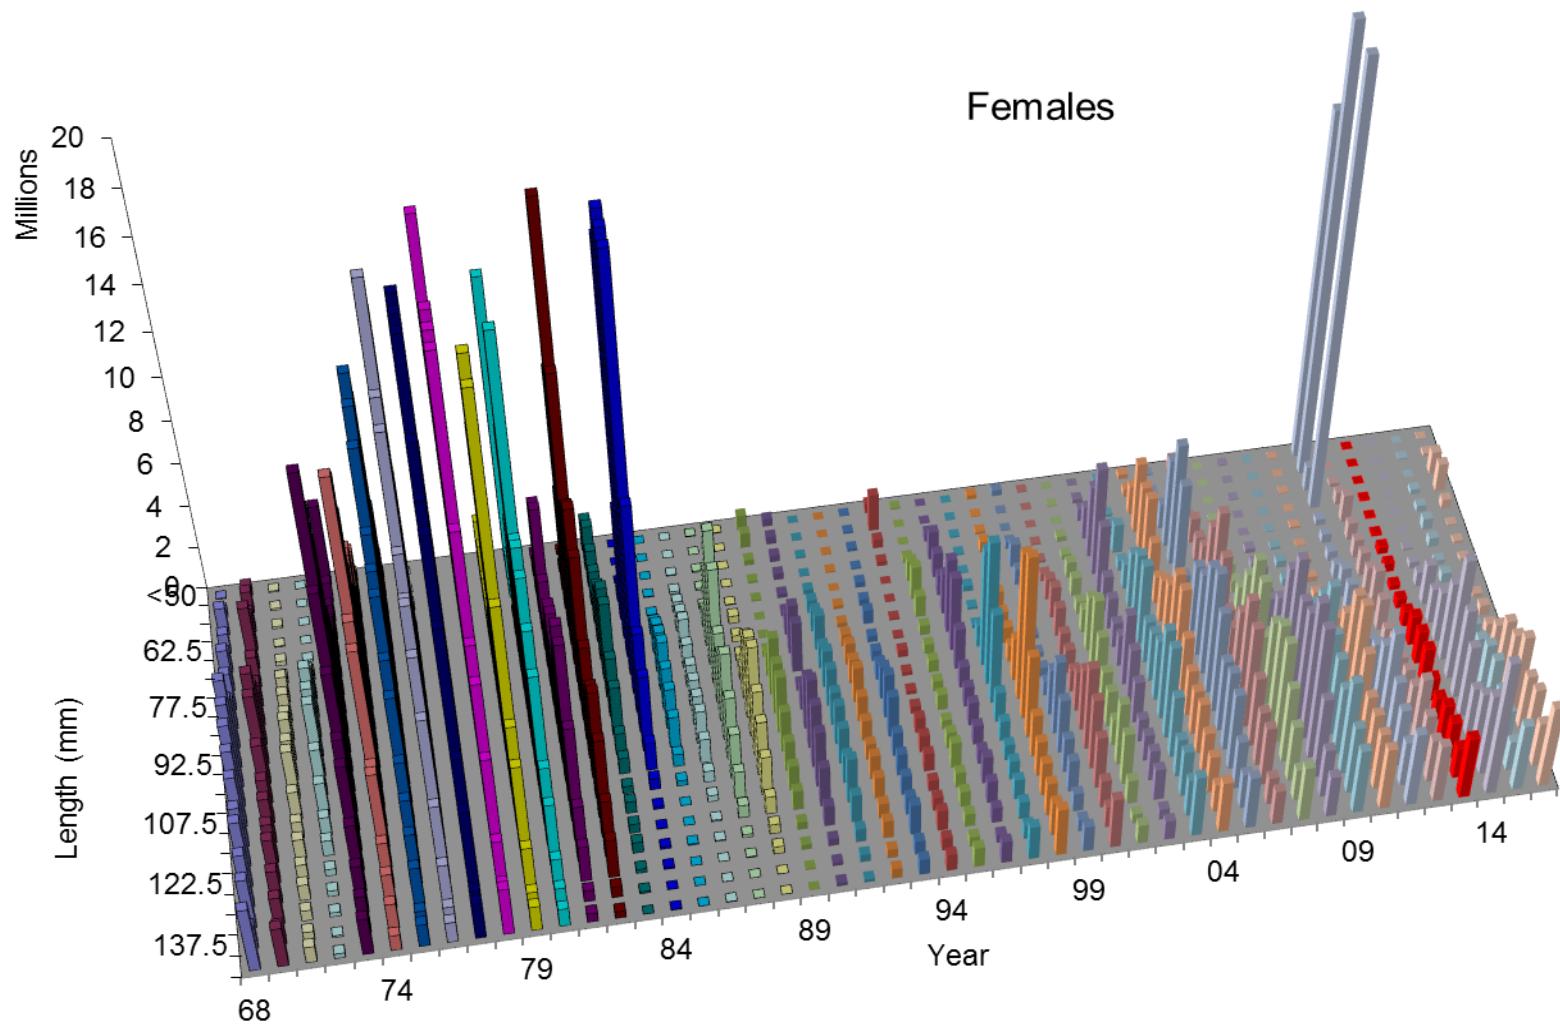

Figure 5b. Survey abundances by 5 mm carapace length bin for female Bristol Bay red king crab from 1968 to 2016.

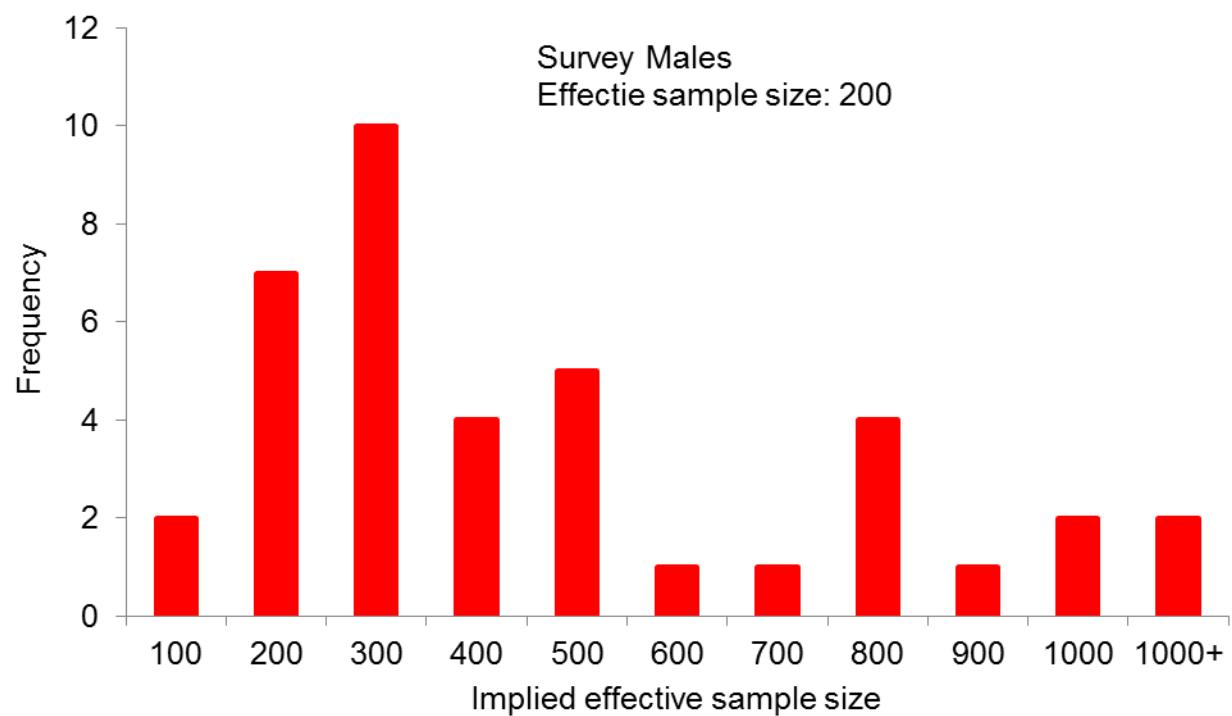

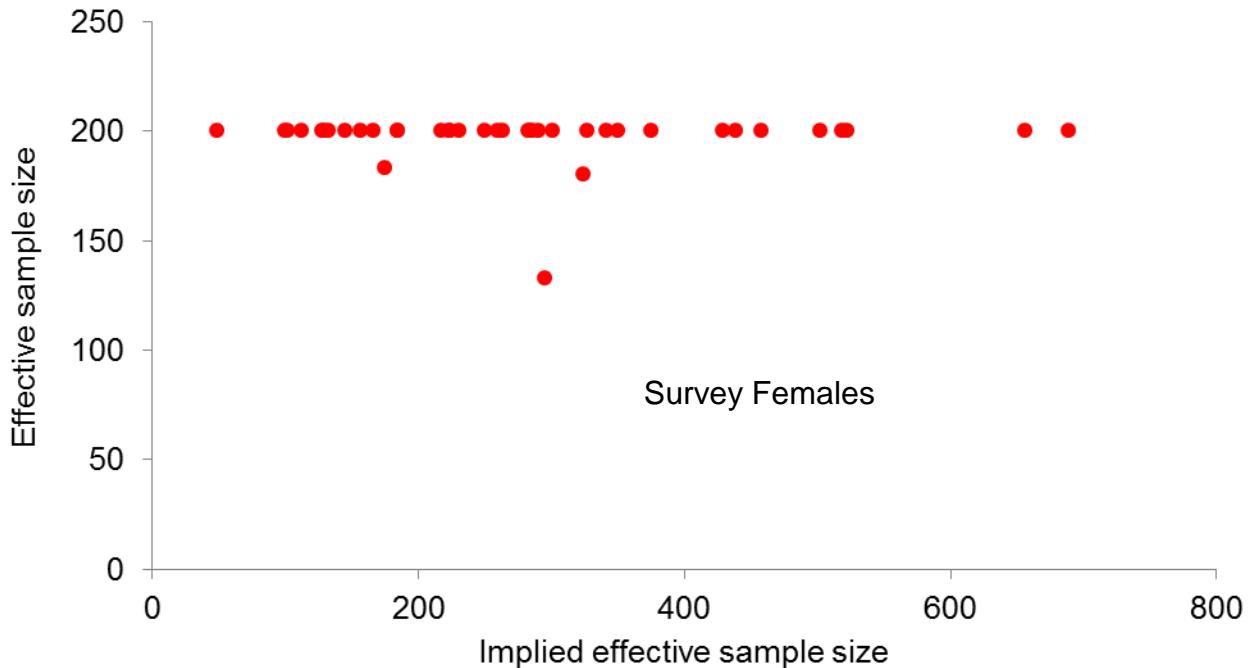

Figure 6. Relationship between implied effective sample sizes (section 3(a)(5)(i)) and effective sample sizes (see effective sample sizes for scenario 1) for length/sex composition data with scenario 1: trawl survey data.

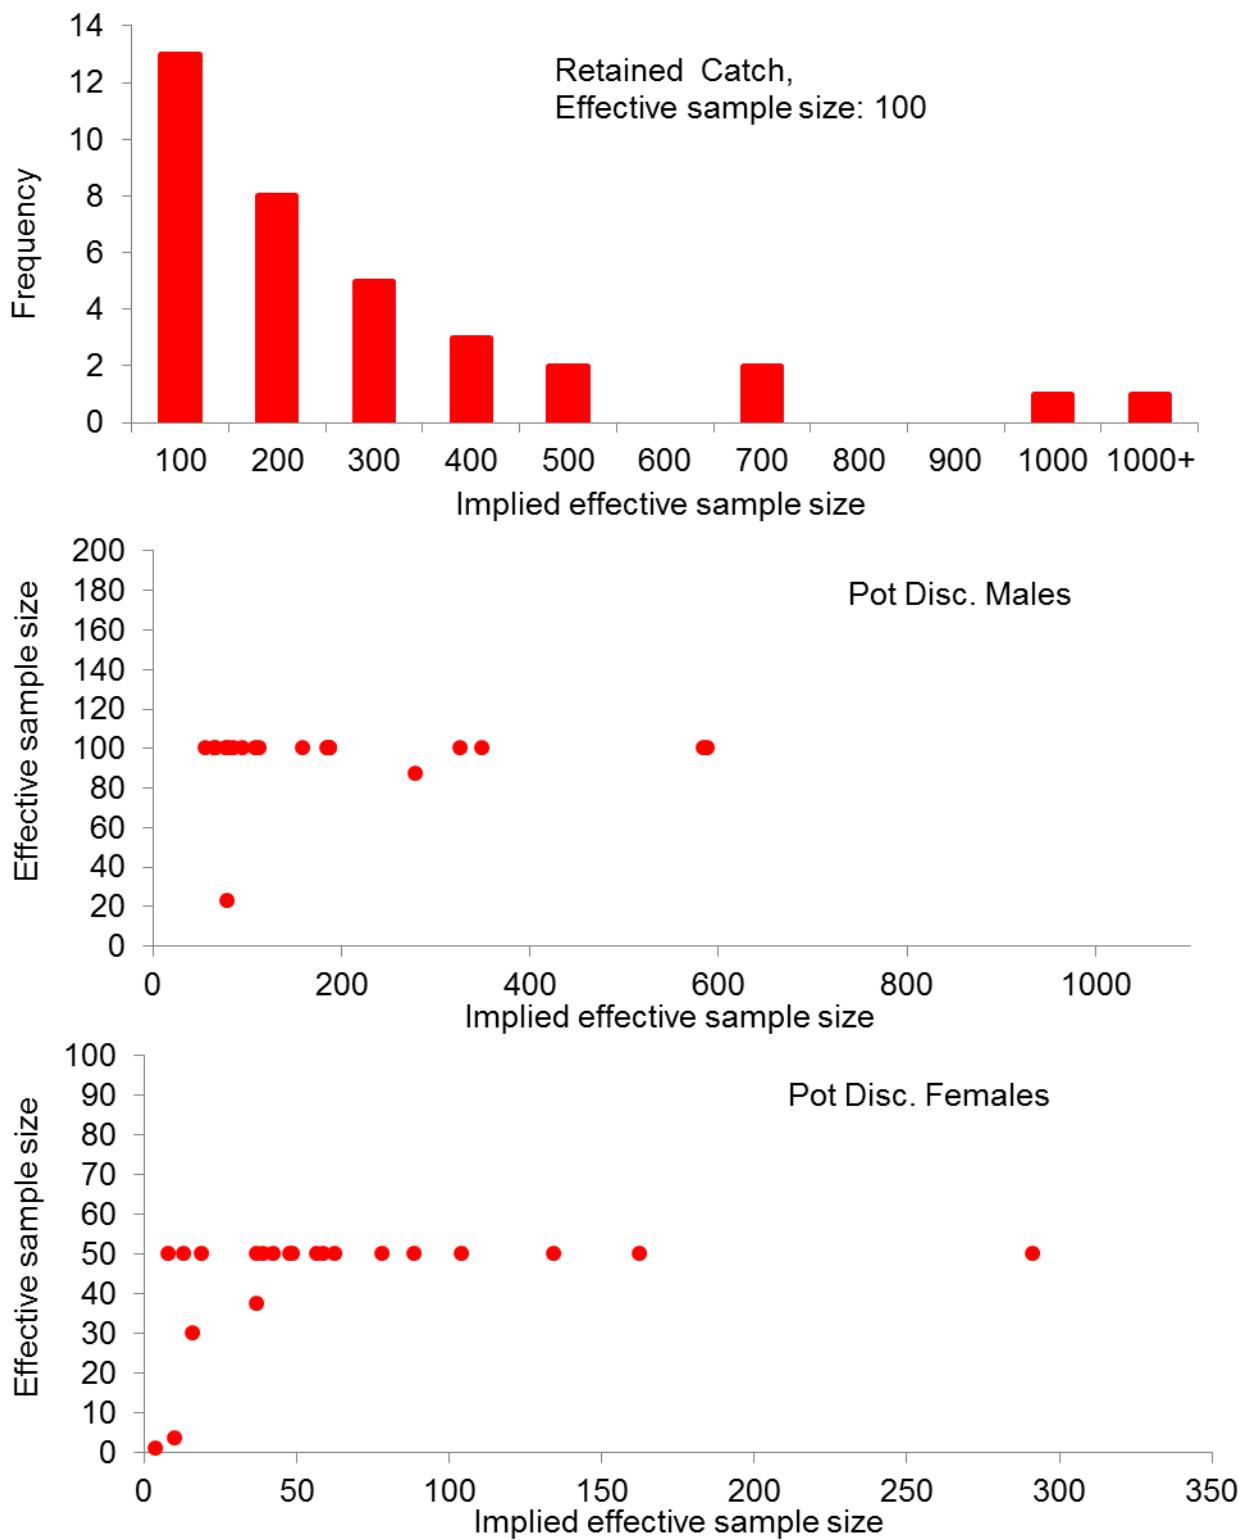

Figure 7. Relationship between implied effective sample sizes (section 3(a)(5)(i)) and effective sample sizes (see effective sample sizes for scenario 1) for length/sex composition data with scenario 1: directed pot fishery data.

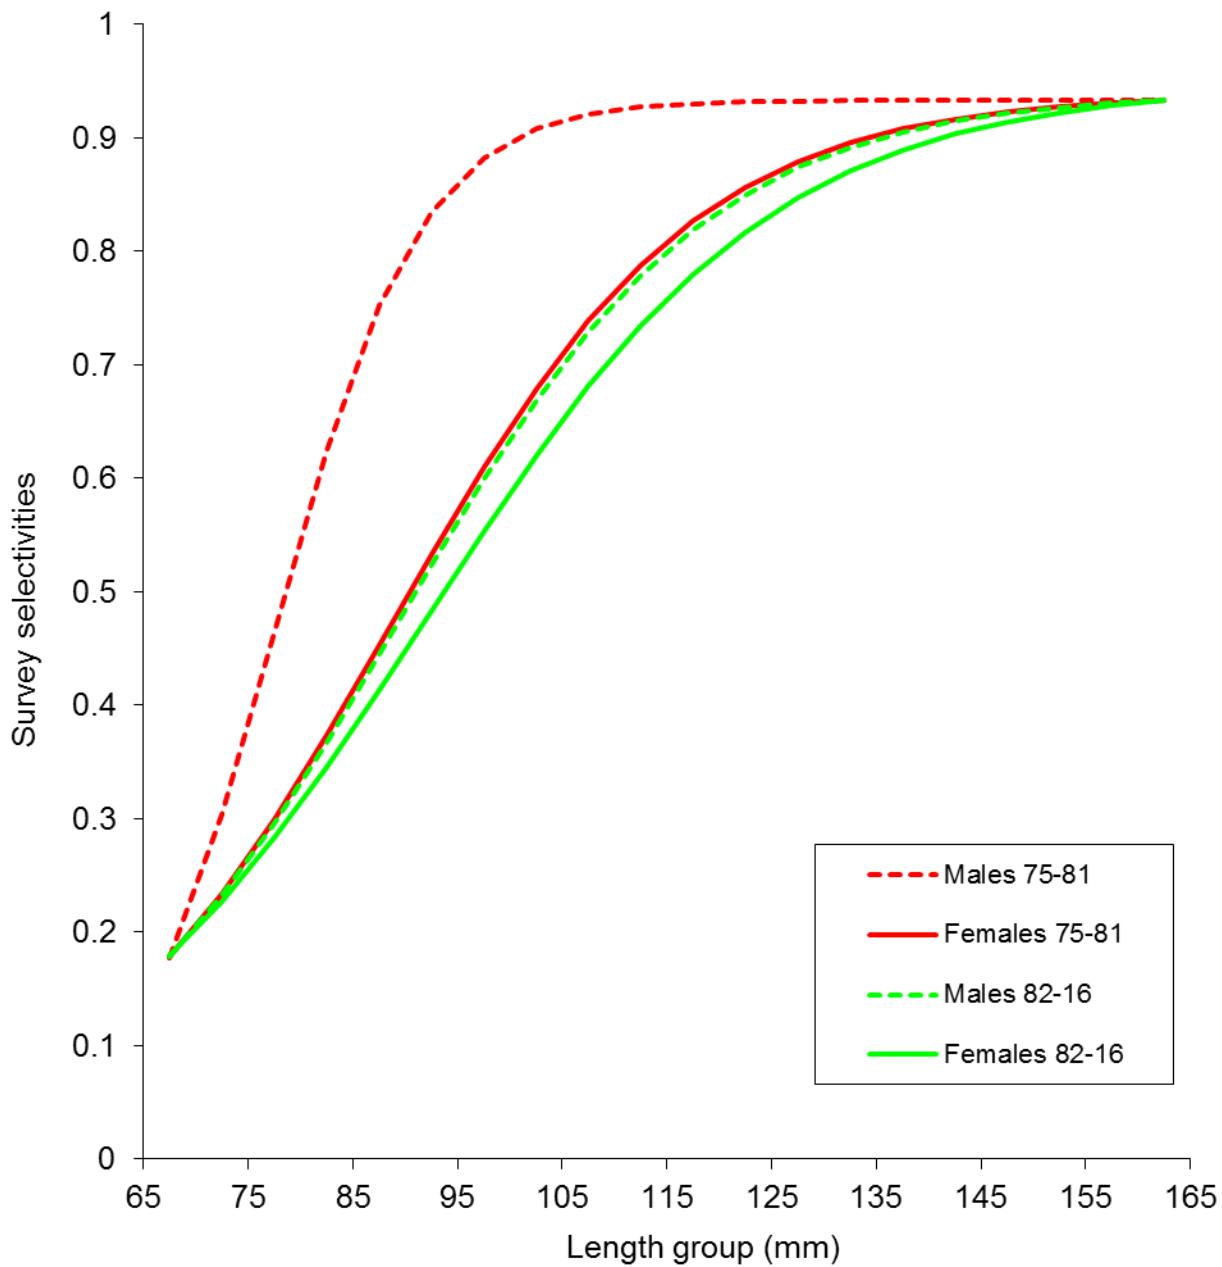

Figure 8a(1). Estimated trawl survey selectivities under scenario 1. Pot and trawl handling mortality rates were assumed to be 0.2 and 0.8, respectively.

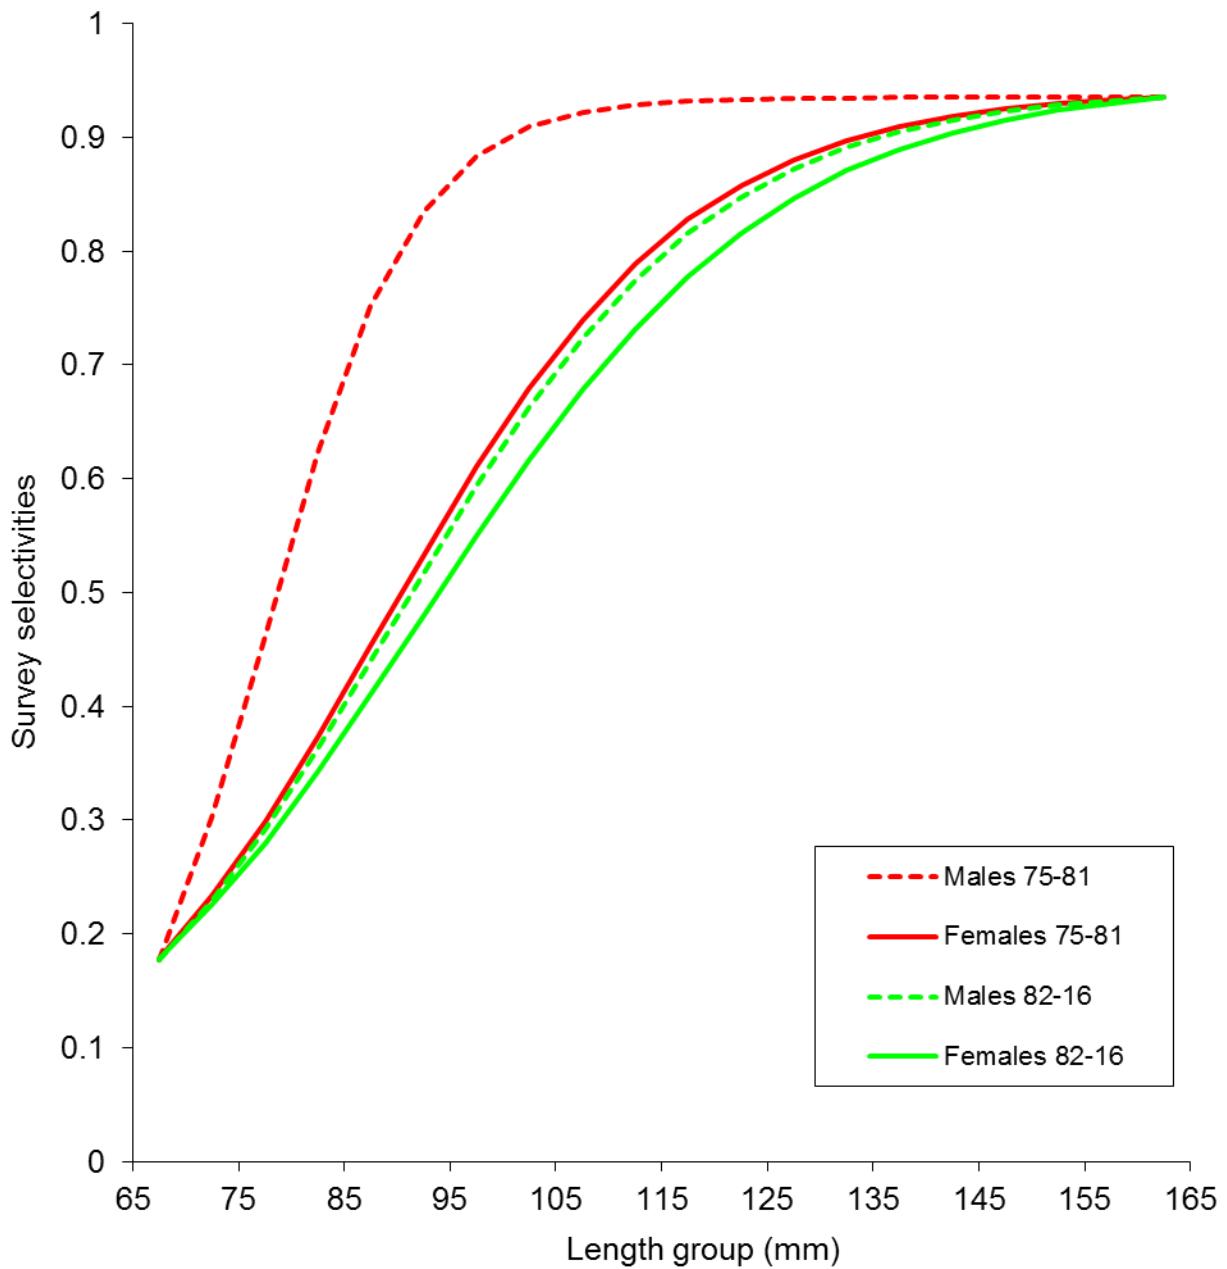

Figure 8a(1n). Estimated trawl survey selectivities under scenario 1n. Pot and trawl handling mortality rates were assumed to be 0.2 and 0.8, respectively.

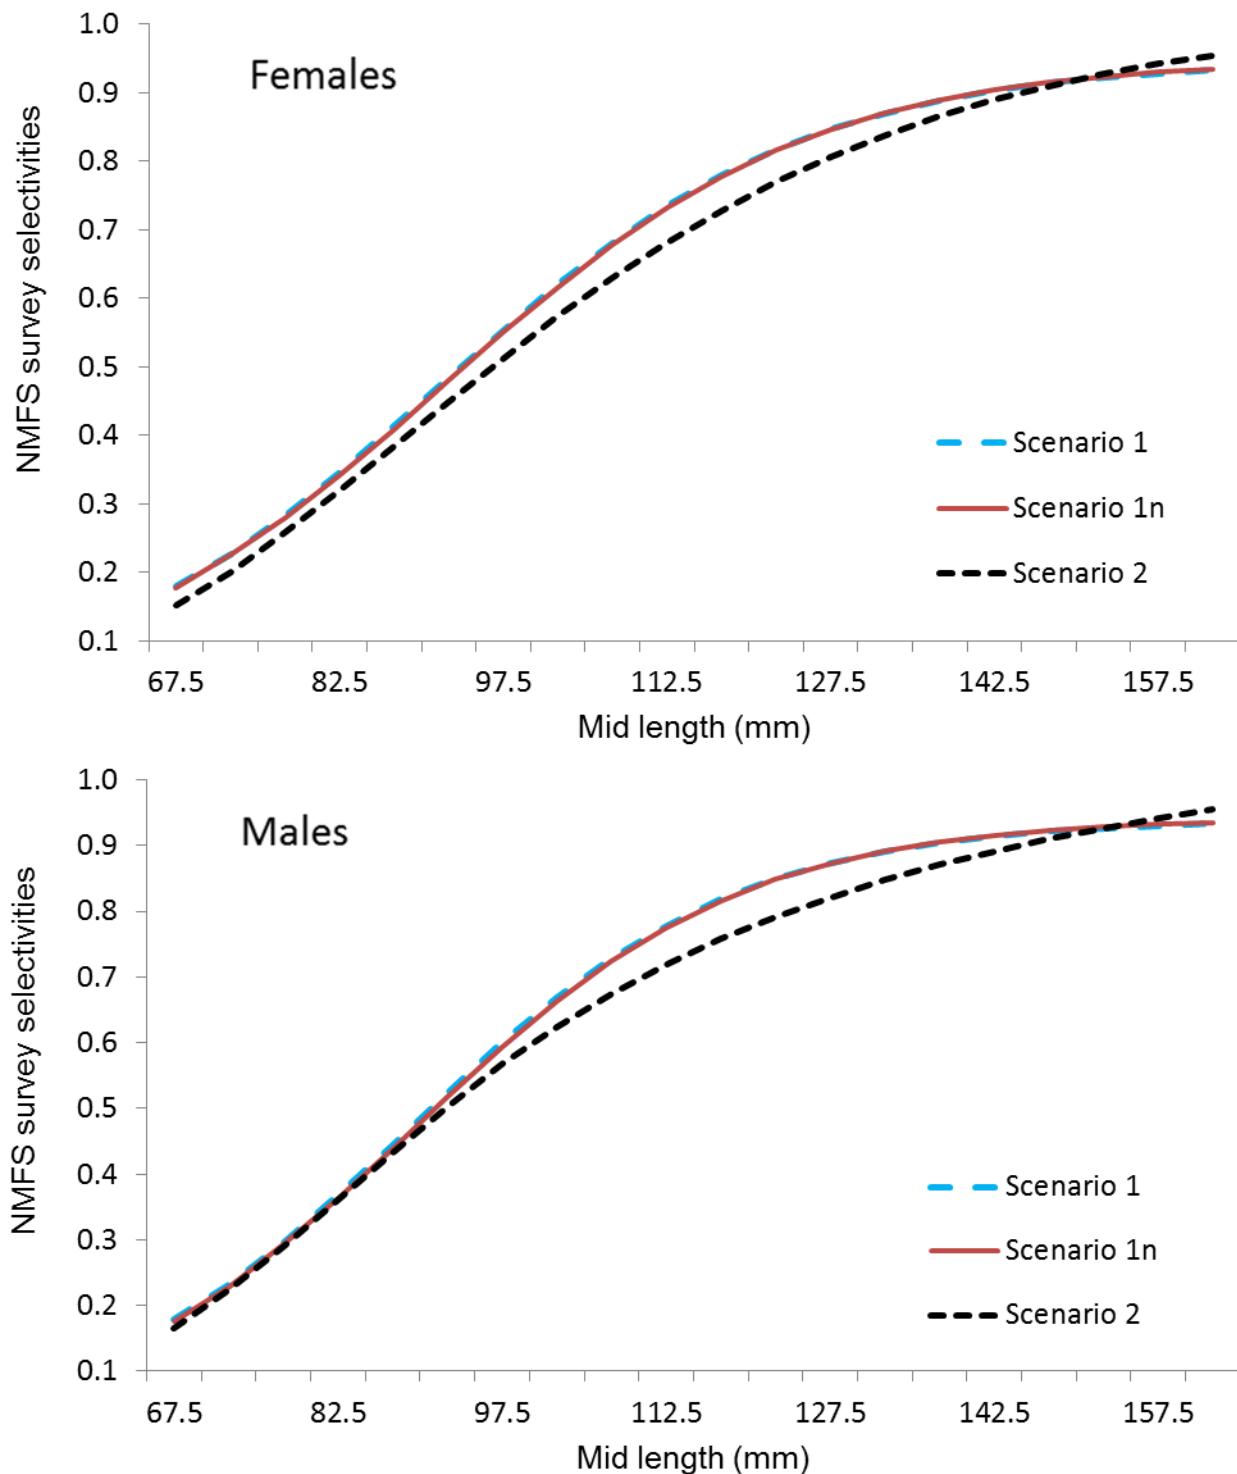

Figure 8b. Comparisons of estimated NMFS trawl survey selectivities for period 1982-2016 under scenarios 1, 1n and 2. Pot and trawl handling mortality rates were assumed to be 0.2 and 0.8, respectively.

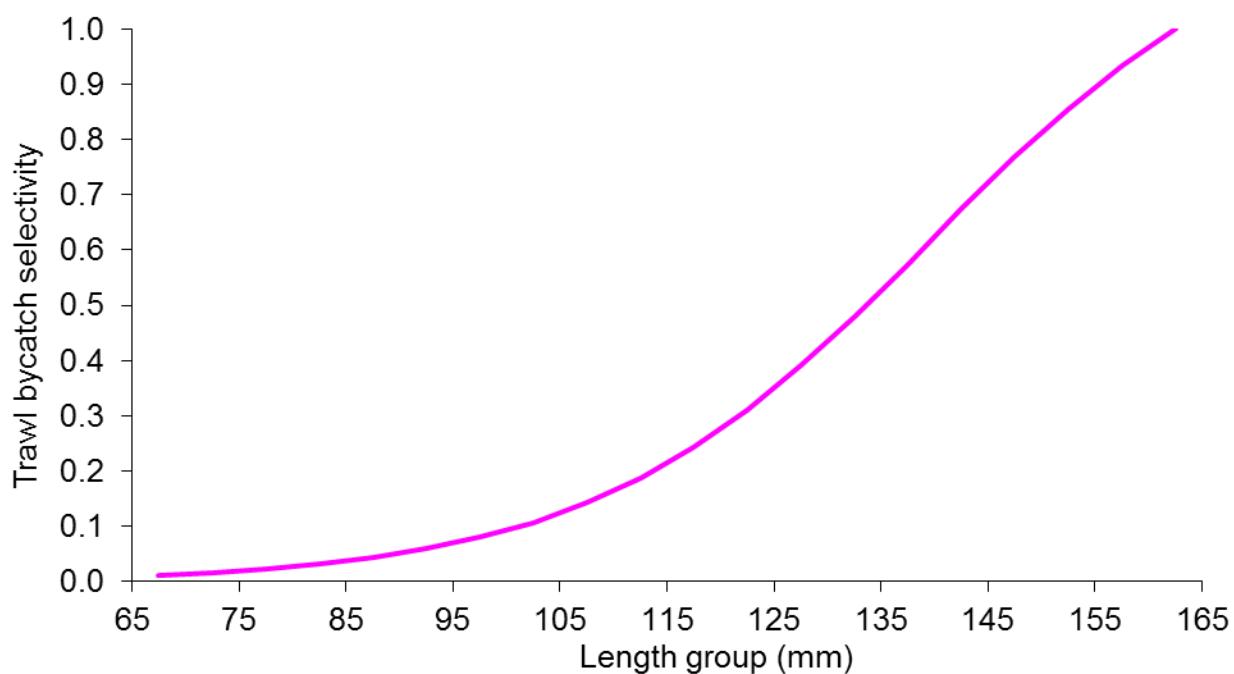

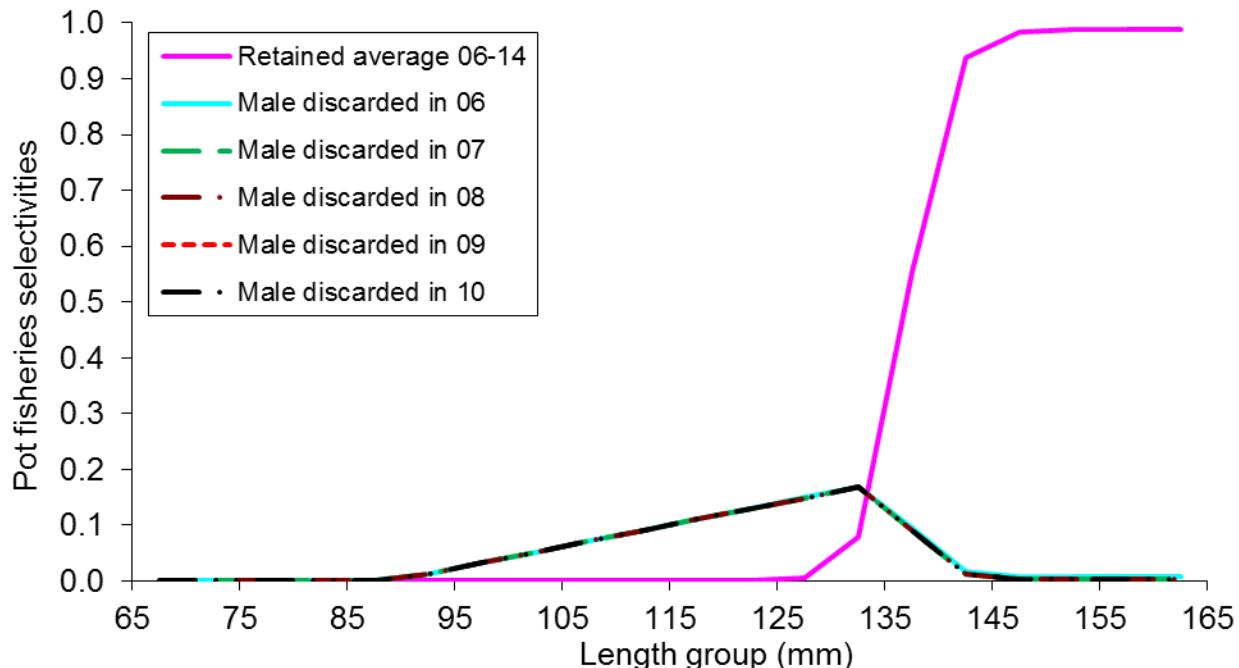

Figure 8c. Estimated pot fishery selectivities and groundfish trawl bycatch selectivities under scenario 1. Pot and trawl handling mortality rates were assumed to be 0.2 and 0.8, respectively.

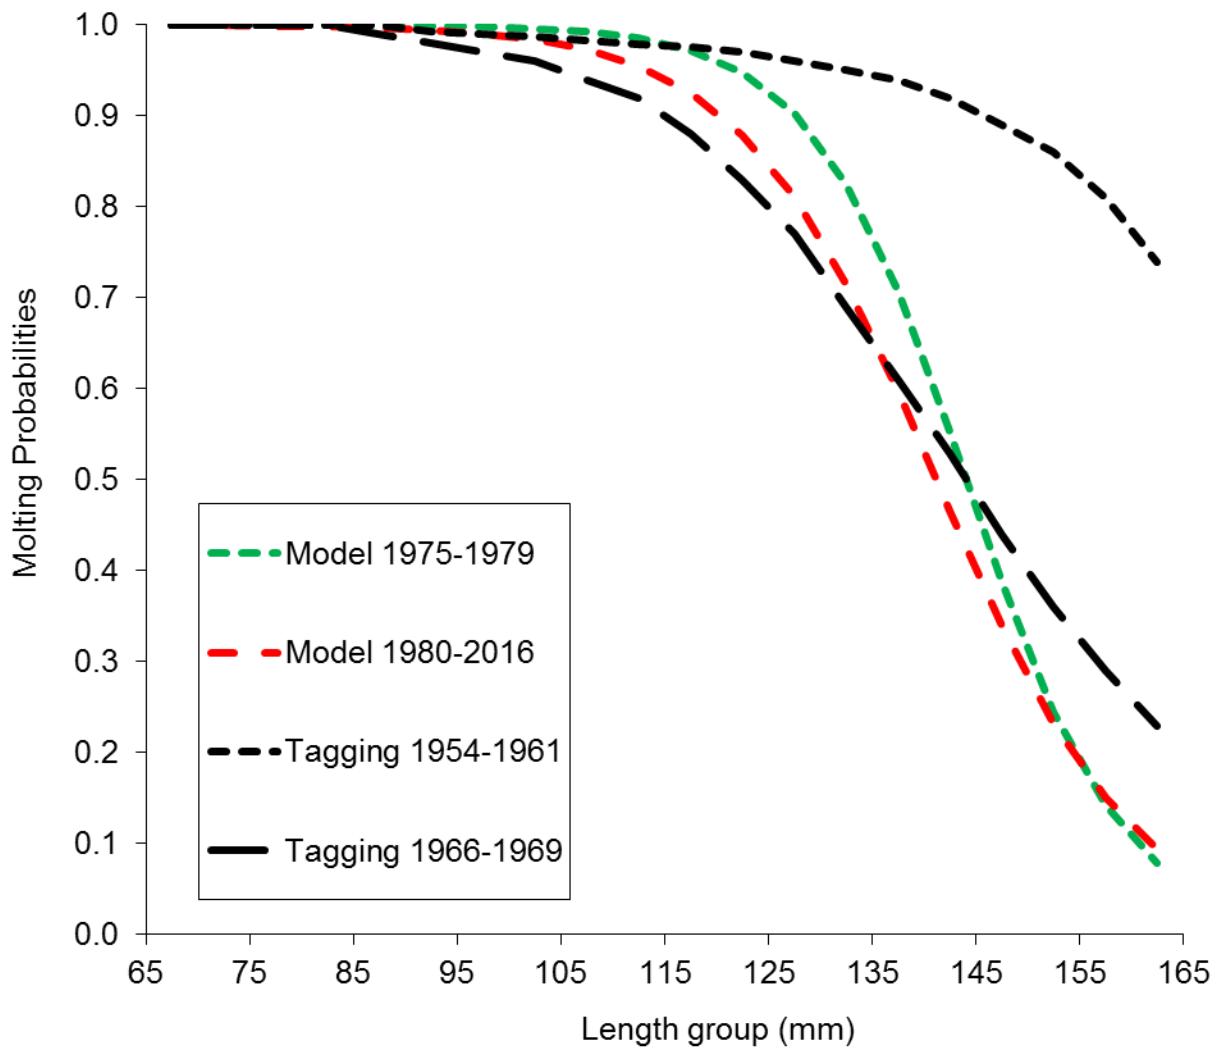

Figure 9(1). Comparison of estimated probabilities of molting of male red king crab in Bristol Bay for different periods. Molting probabilities for periods 1954-1961 and 1966-1969 were estimated by Balsiger (1974) from tagging data. Molting probabilities for 1975-2016 were estimated with a length-based model with a pot handling mortality rate of 0.2 under scenario 1.

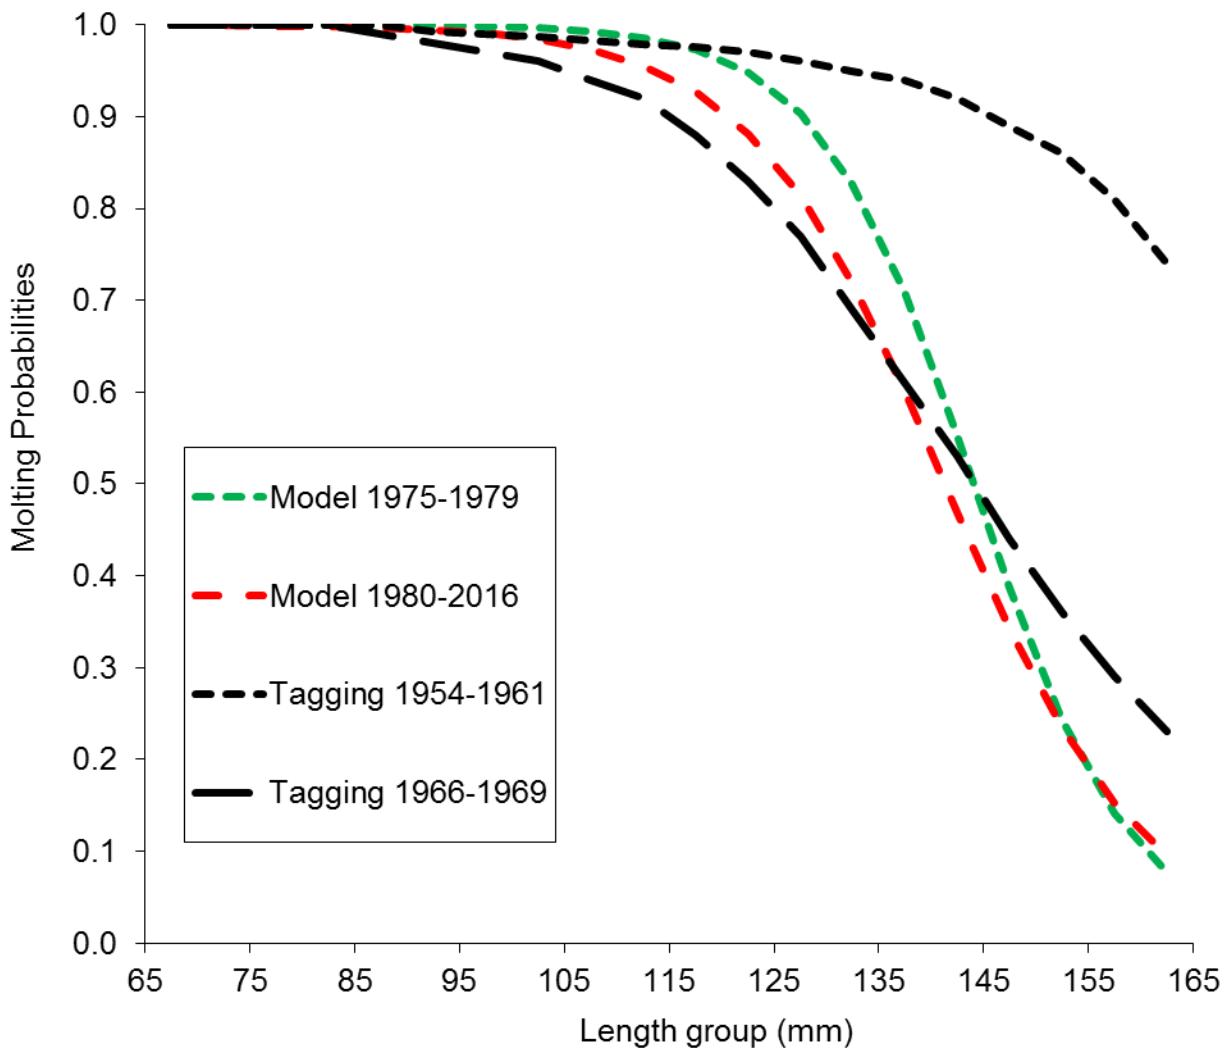

Figure 9(1n). Comparison of estimated probabilities of molting of male red king crab in Bristol Bay for different periods. Molting probabilities for periods 1954-1961 and 1966-1969 were estimated by Balsiger (1974) from tagging data. Molting probabilities for 1975-2016 were estimated with a length-based model with pot handling mortality rate of 0.2 under scenario 1n.

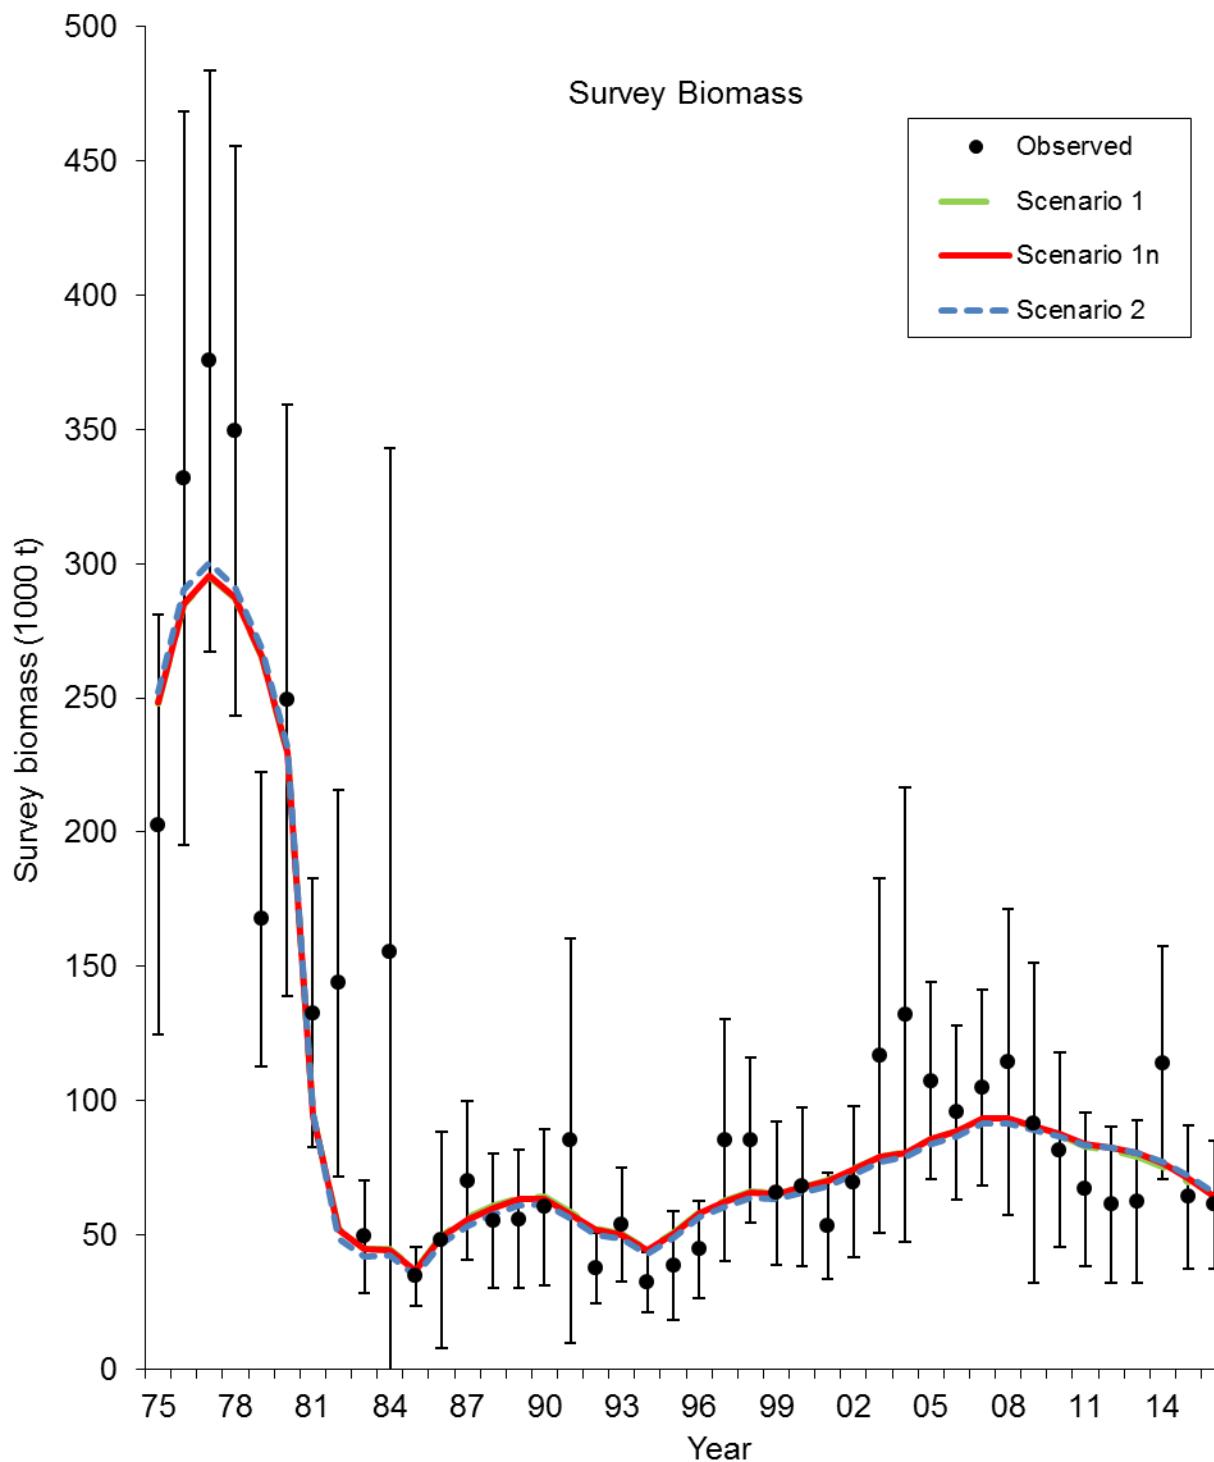

Figure 10a(1, 1n & 2). Comparisons of area-swept estimates of total survey biomass and model prediction for model estimates in 2016 under scenarios 1, 1n and 2. Pot and trawl handling mortality rates were assumed to be 0.2 and 0.8, respectively. The error bars are plus and minus 2 standard deviations.

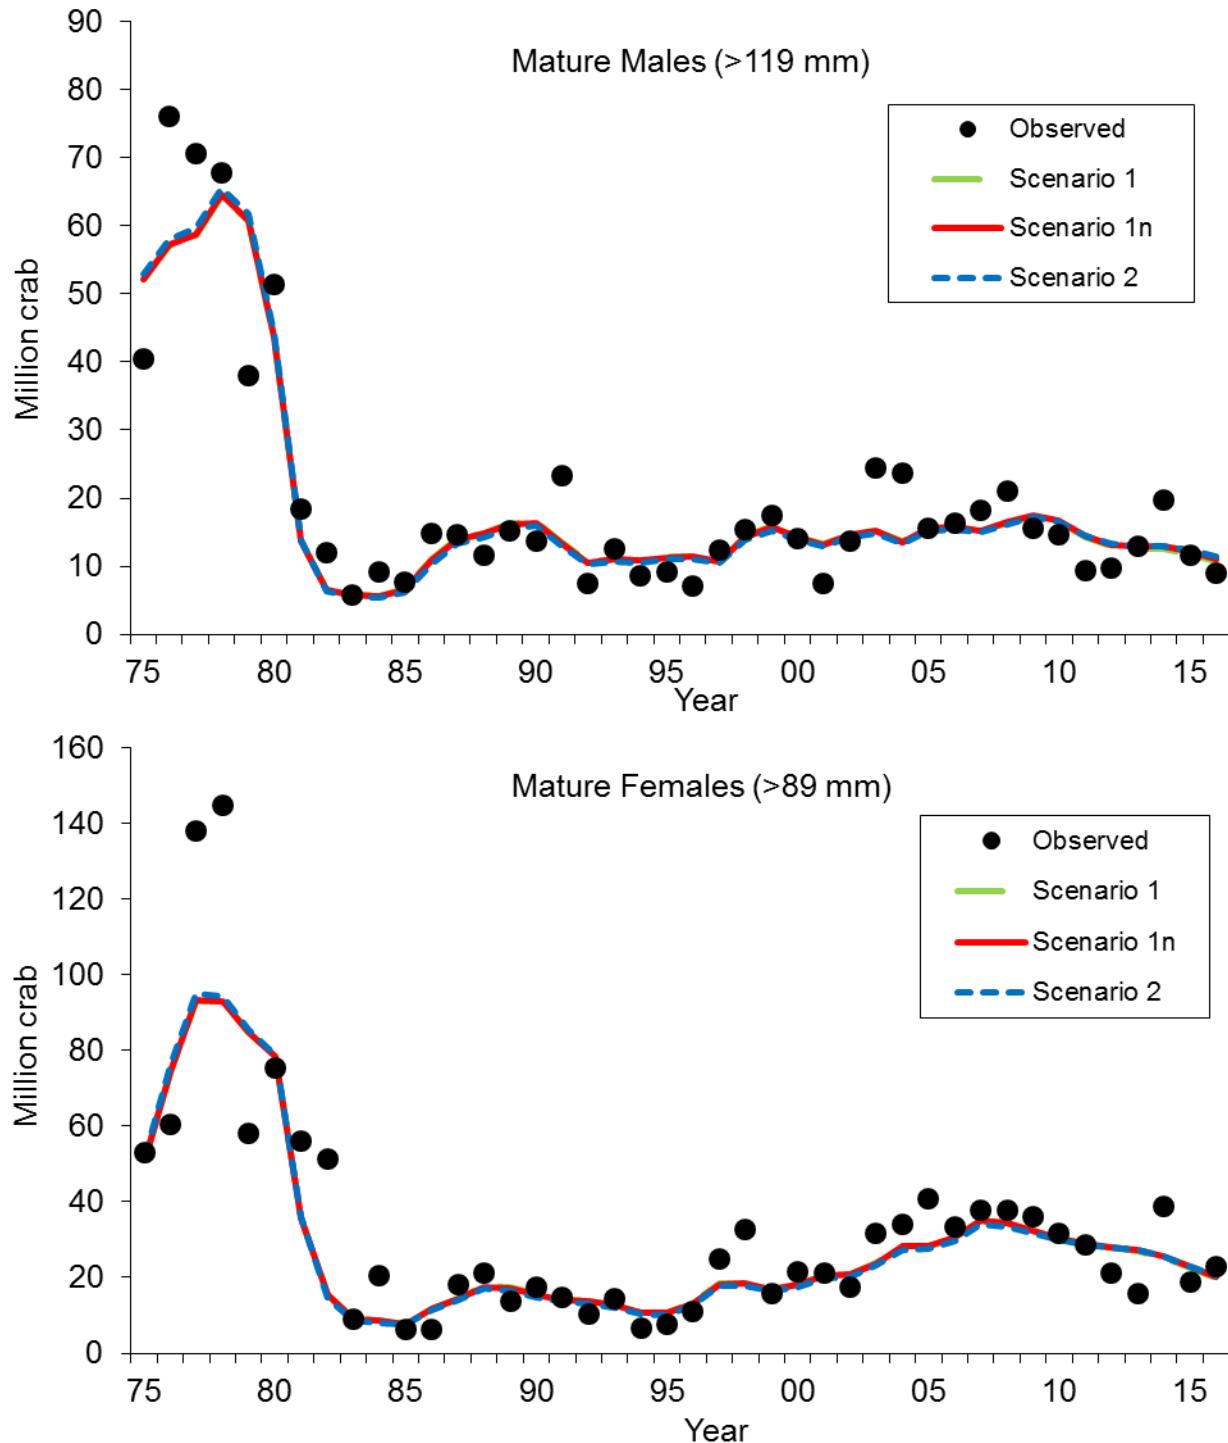

Figure 10b(1, 1n & 2). Comparisons of area-swept estimates of male (>119 mm) and female (>89 mm) abundance and model prediction for model estimates in 2014 under scenarios 1, 1n and 2. Pot and trawl handling mortality rates were assumed to be 0.2 and 0.8, respectively.

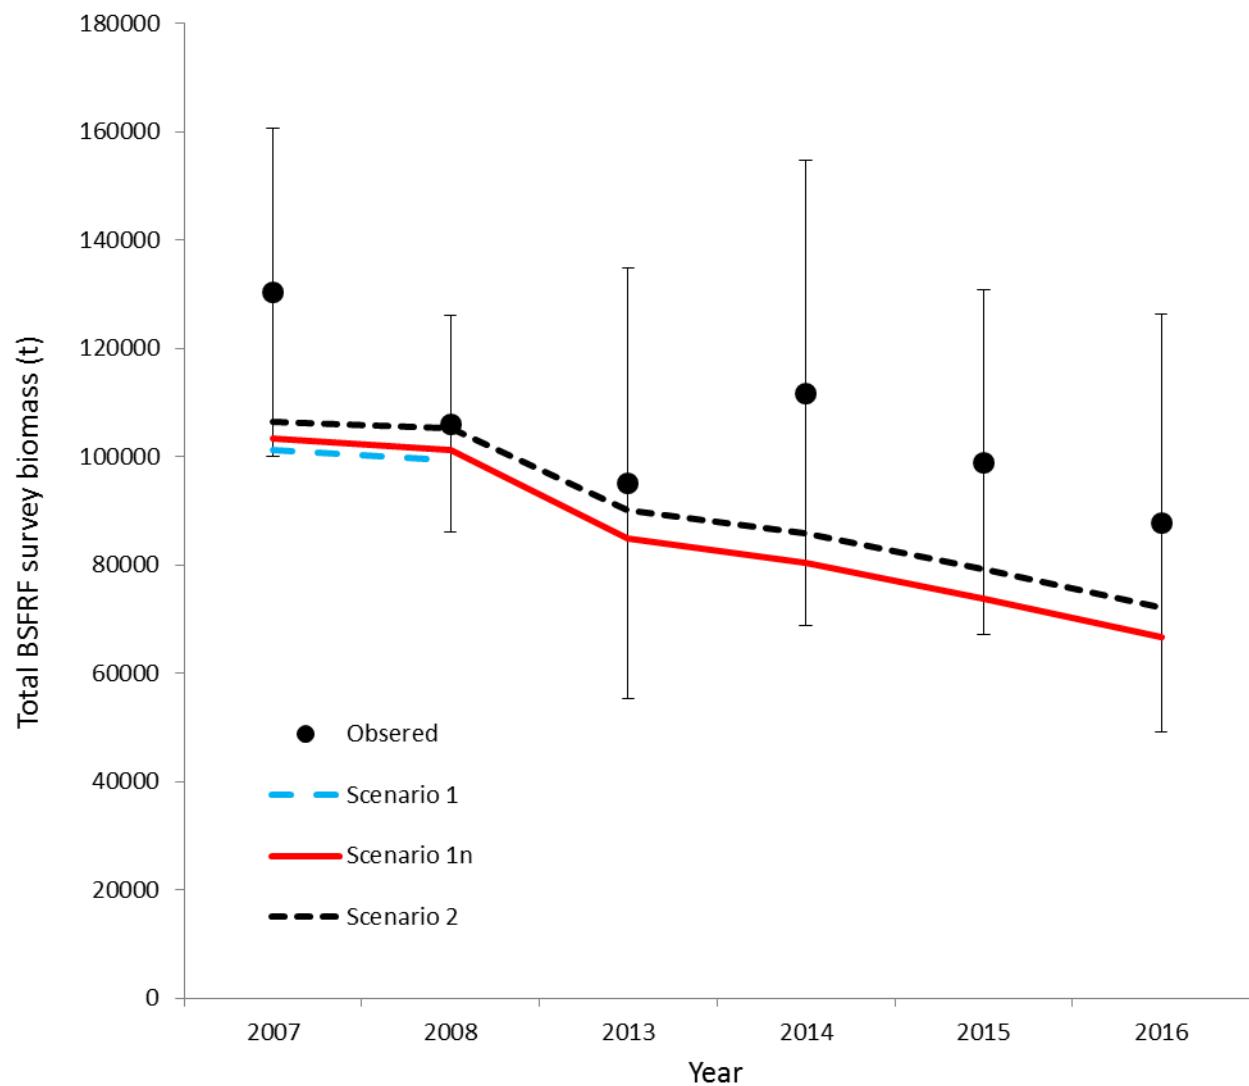

Figure 10c. Comparisons of total survey biomass estimates by the BSFRF survey and the model for model estimates in 2016 (scenarios 1, 1n & 2). The error bars are plus and minus 2 standard deviations of scenario 1n.

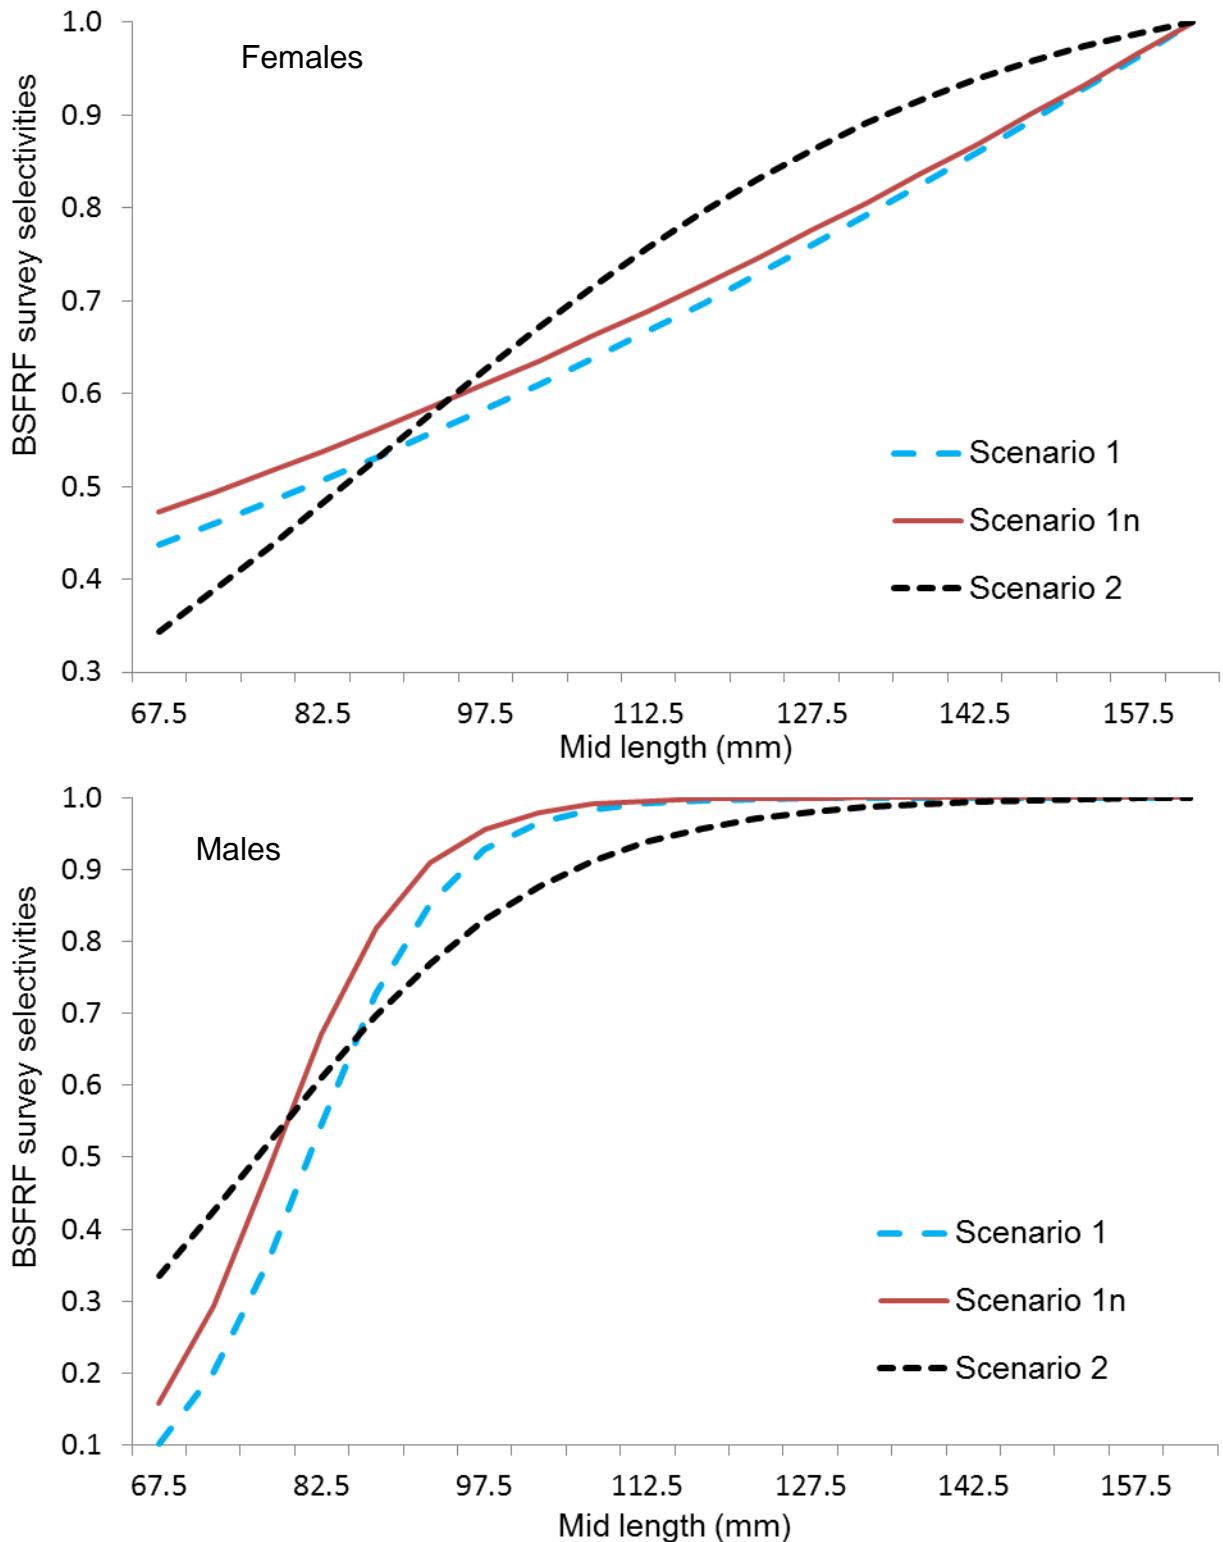

Figure 10d(1, 1n & 2). Comparisons of estimated BSFRF survey selectivities with scenarios 1, 1n and 2. The catchability is assumed to be 1.0.

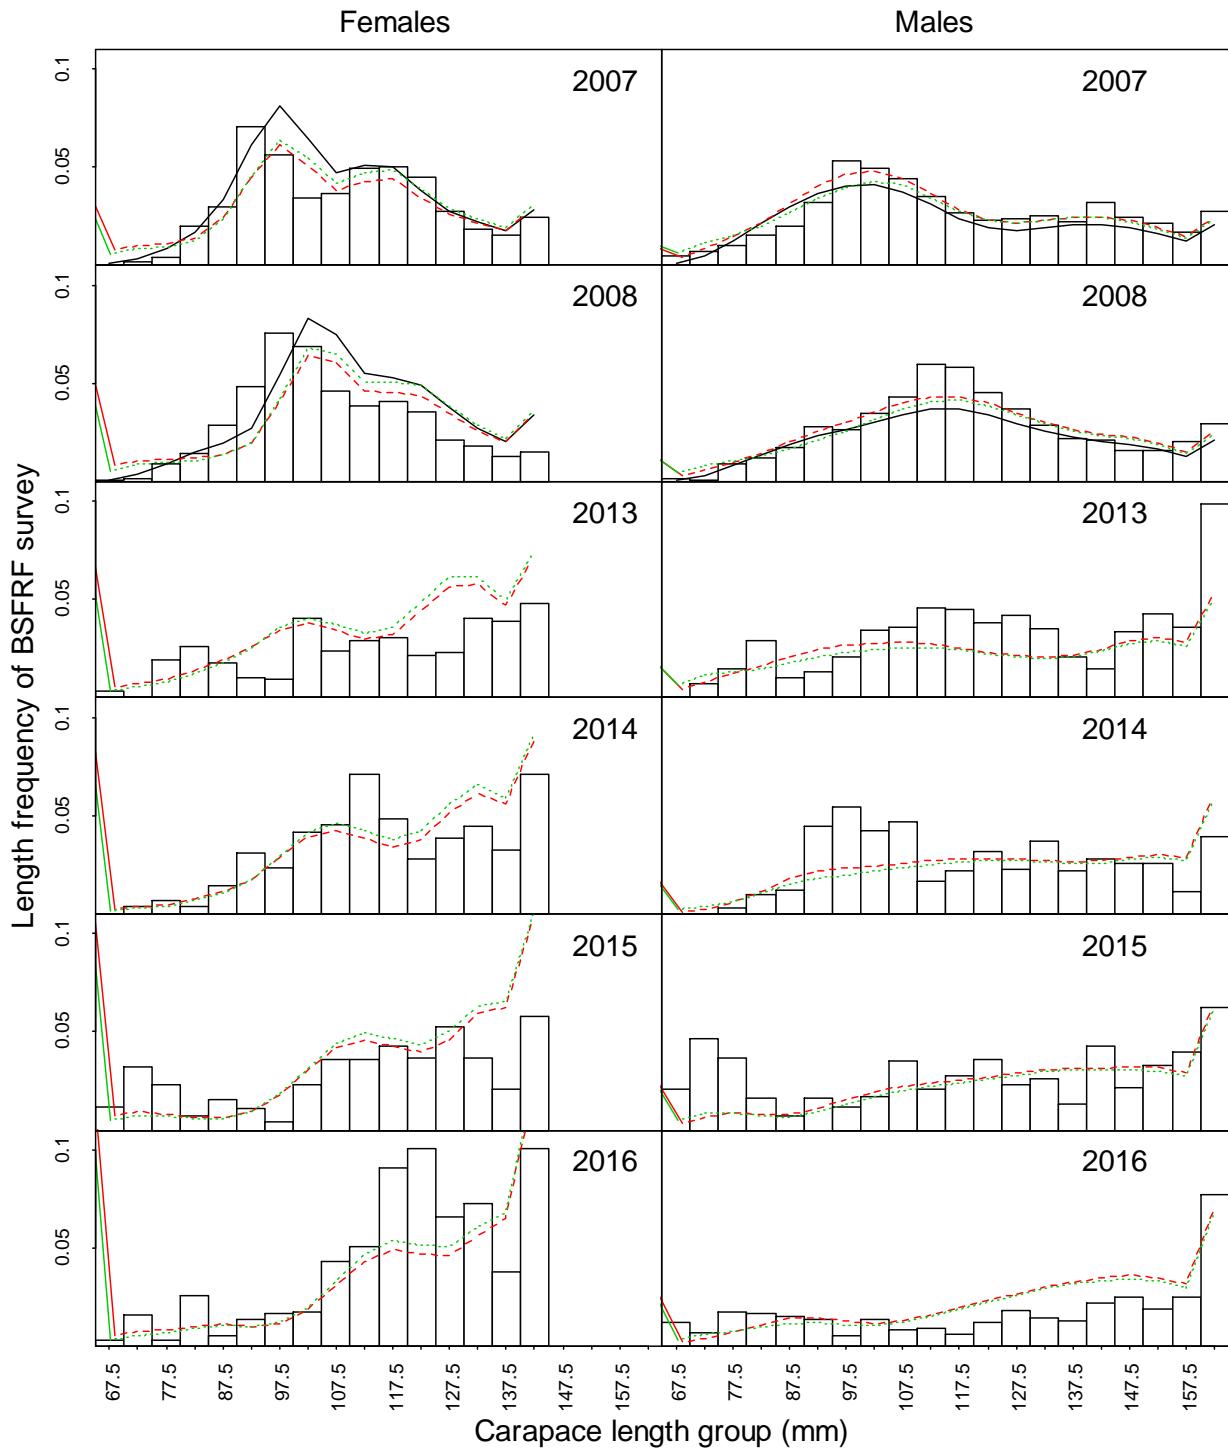

Figure 10e(1, 1n & 2). Comparisons of length compositions by the BSFRF survey and the model estimates during 2007-2008 and 2013-2016 with scenarios 1 (solid black), 1n (dashed red), and 2 (green lines).

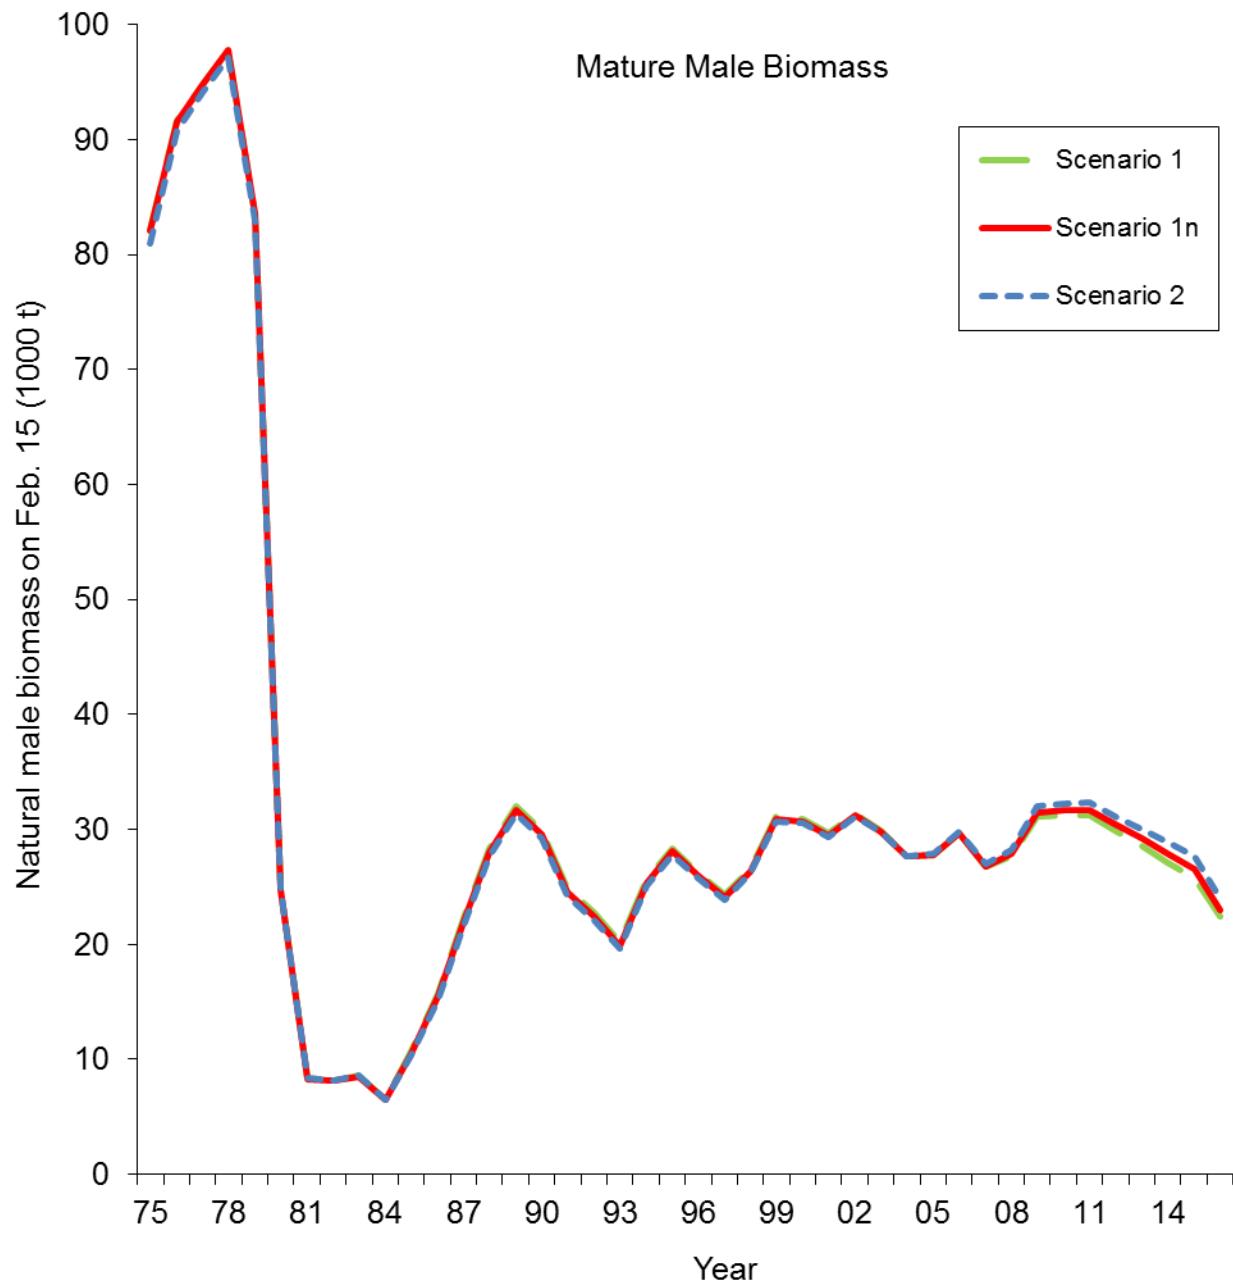

Figure 11. Estimated absolute mature male biomasses during 1975-2016 for scenarios 1, 1n and 2.

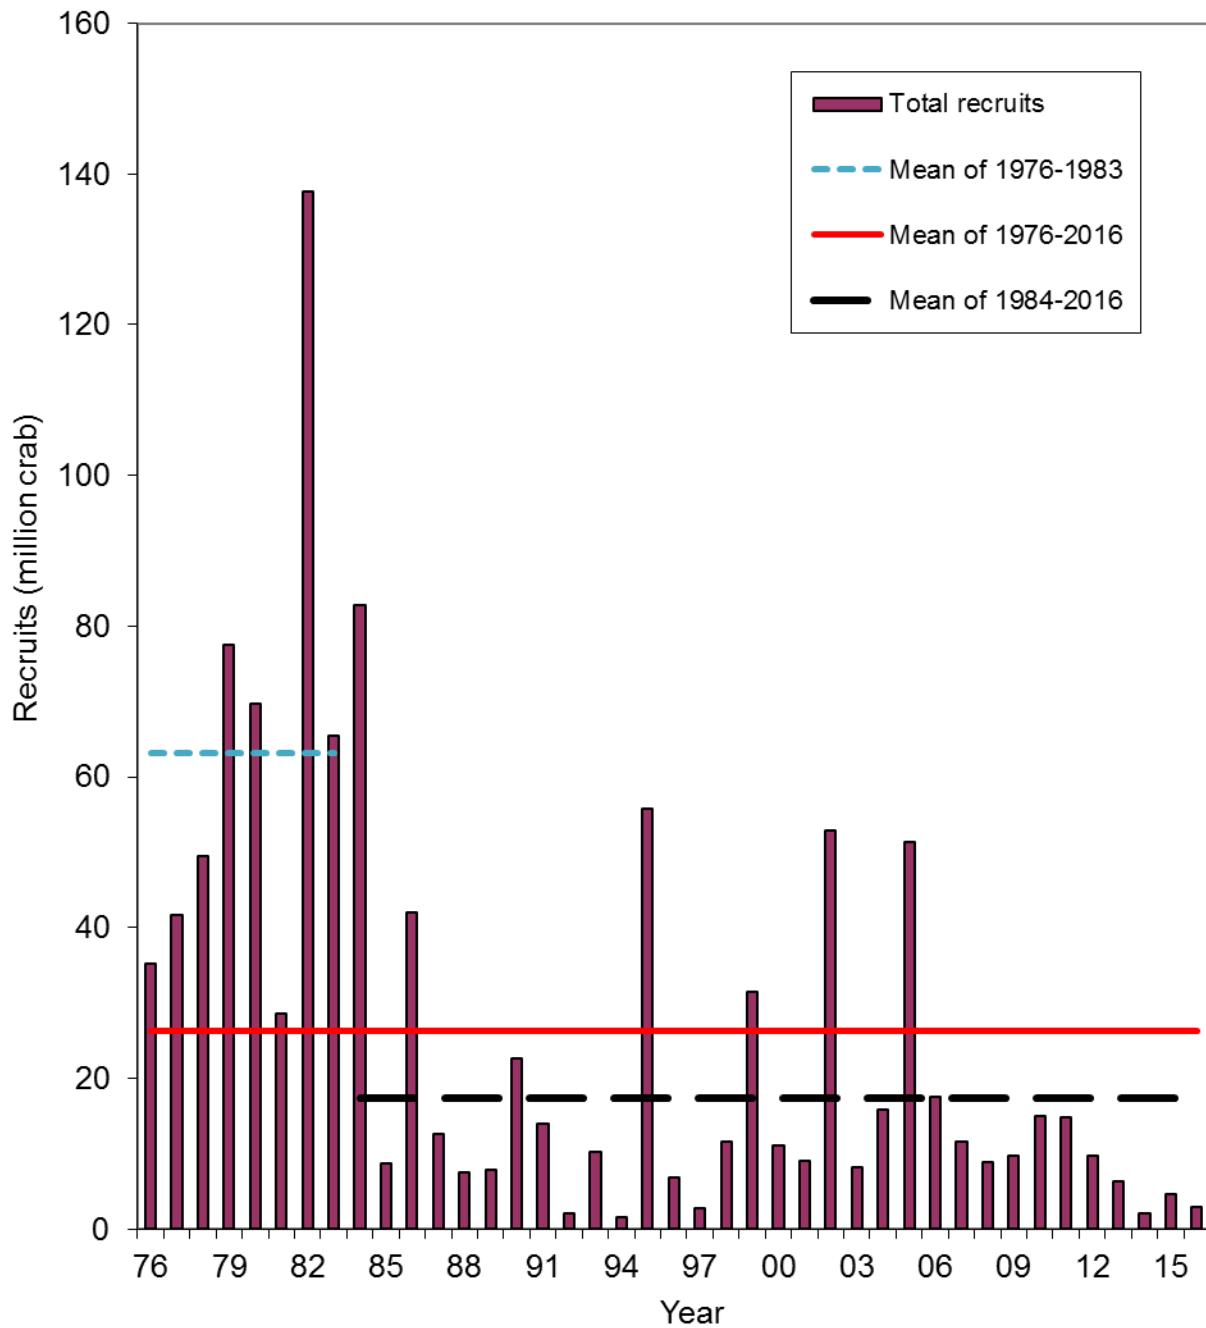

Figure 12(1). Estimated recruitment time series during 1976-2016 with scenario 1. Mean male recruits during 1984-2016 was used to estimate  $B_{35\%}$ .

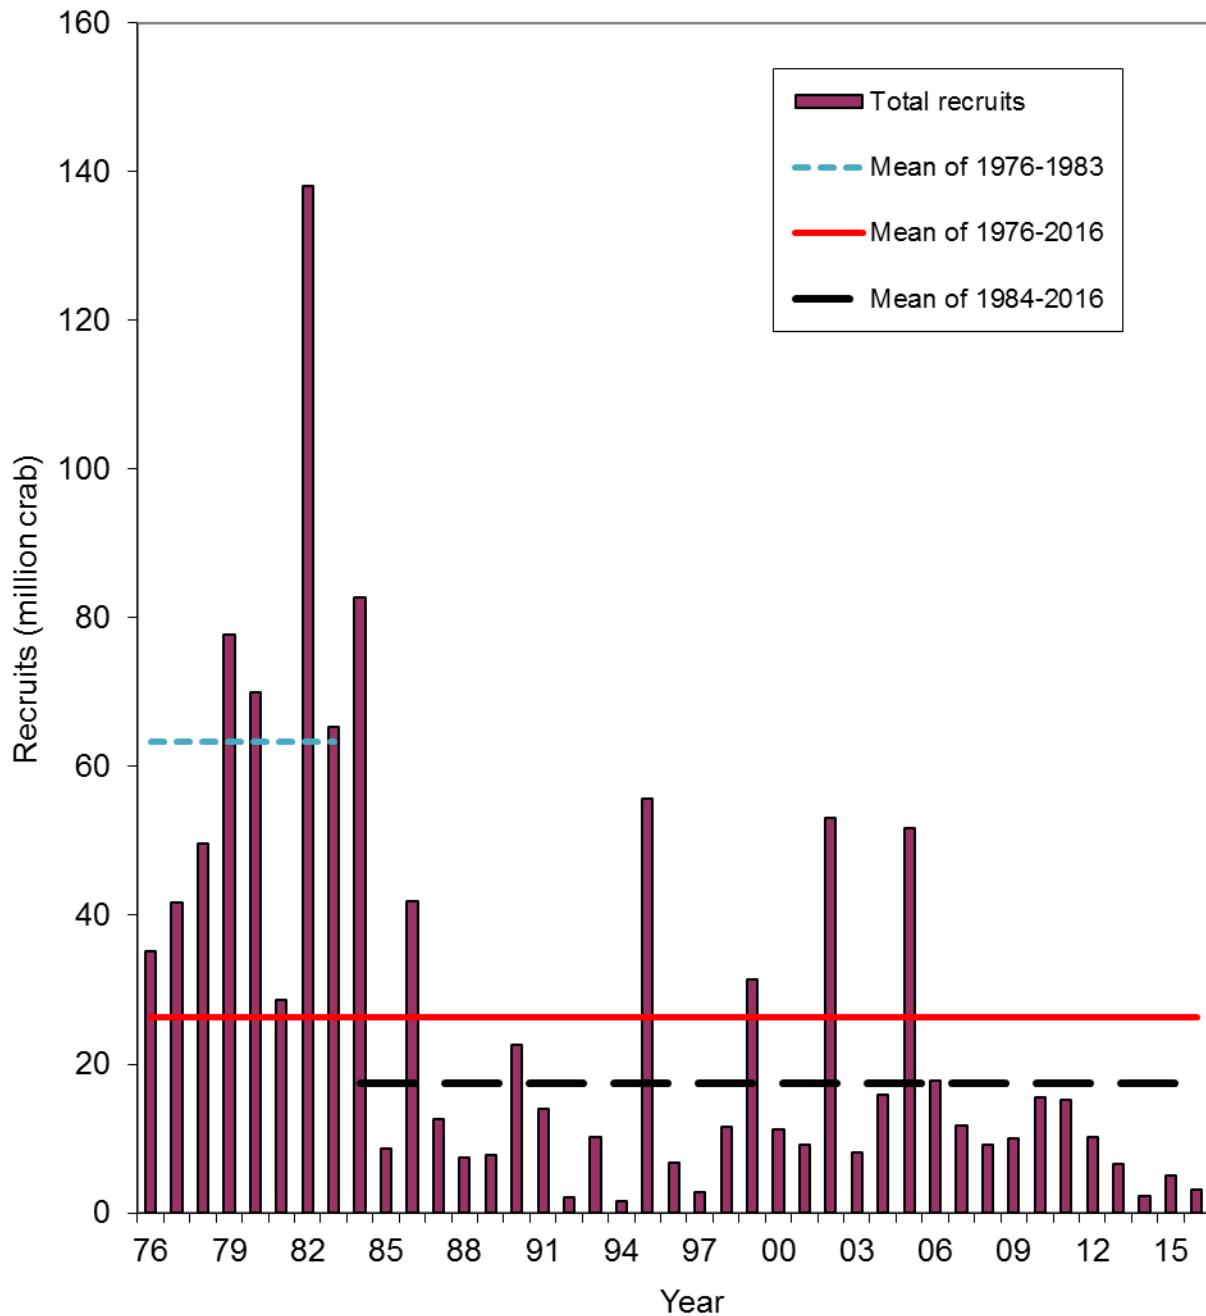

Figure 12(1n). Estimated recruitment time series during 1976-2016 with scenario 1n. Mean male recruits during 1984-2016 was used to estimate  $B_{35\%}$ .

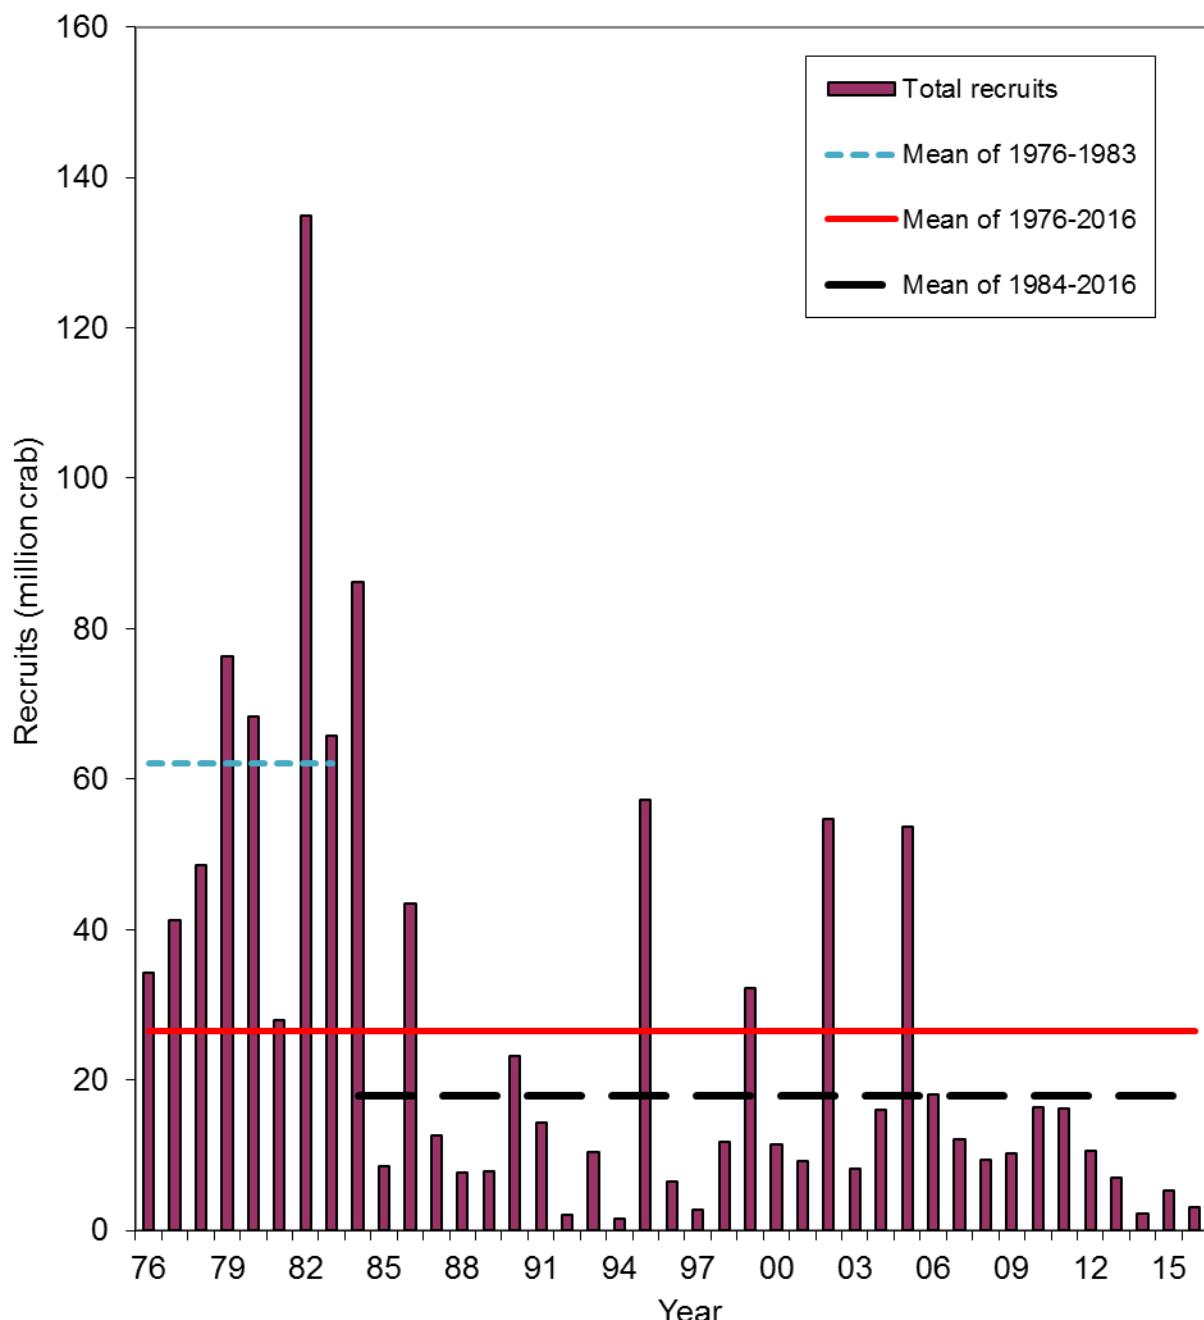

Figure 12(2). Estimated recruitment time series during 1976-2016 with scenario 2. Mean male recruits during 1984-2016 was used to estimate B35%.

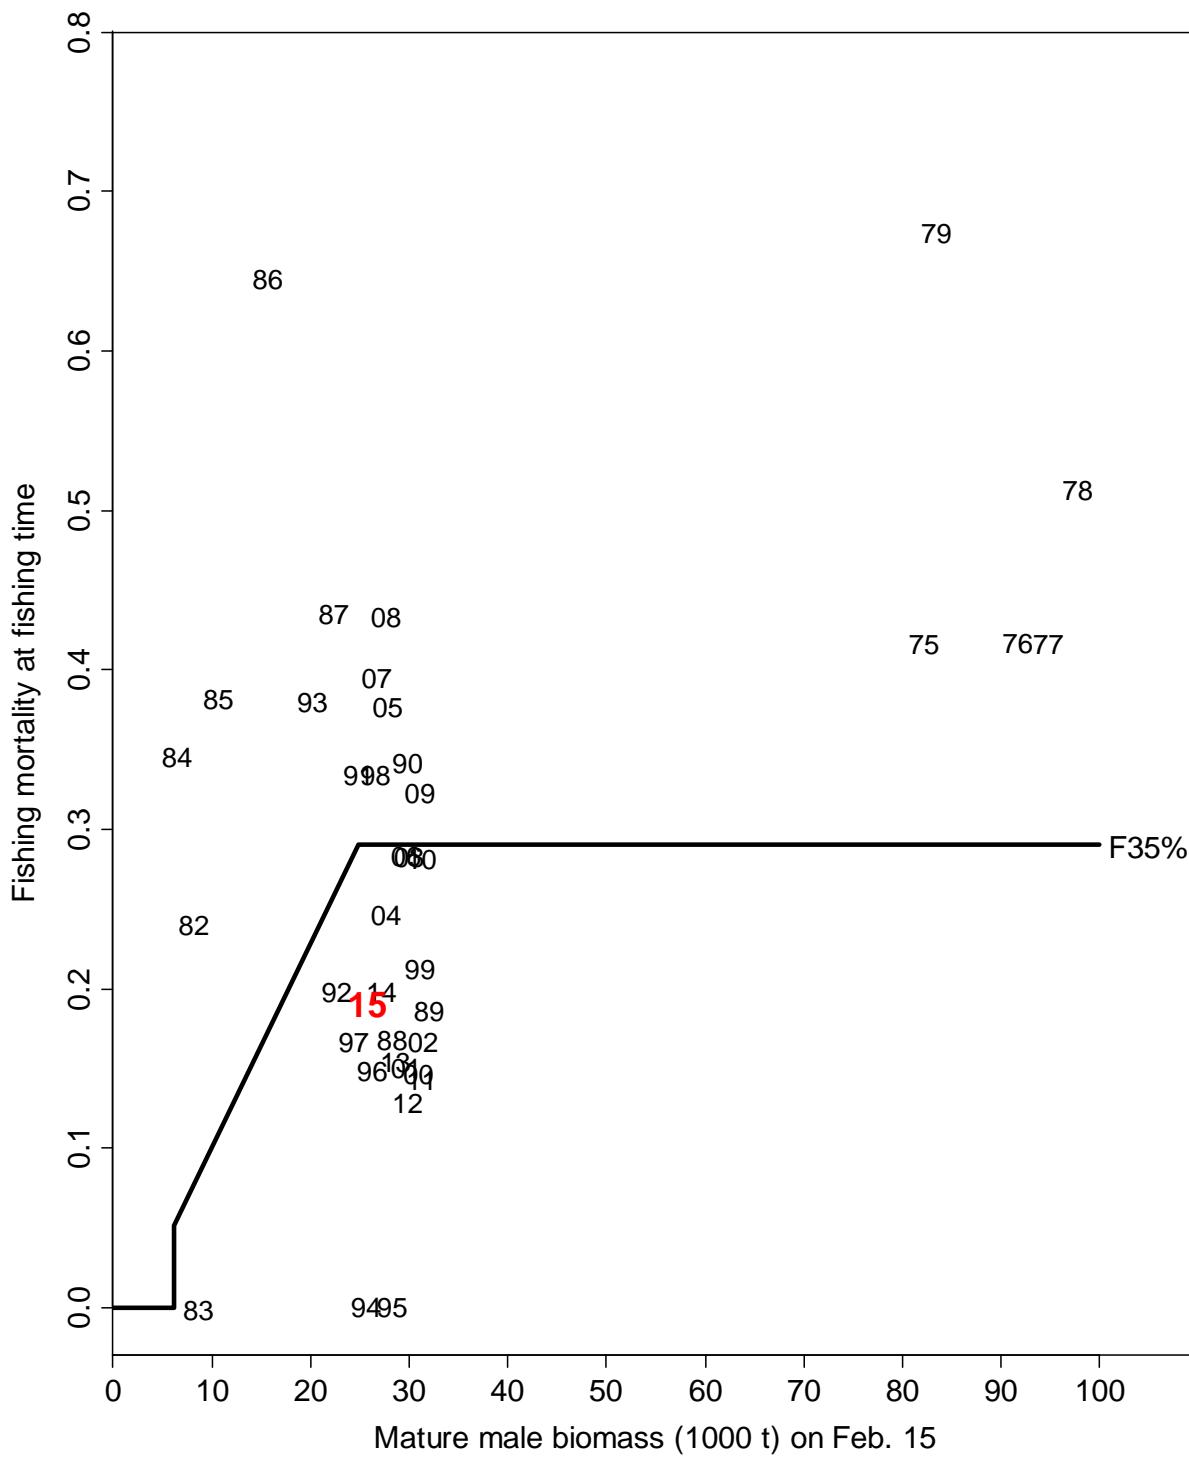

Figure 13(1). Relationships between full fishing mortalities for the directed pot fishery and mature male biomass on Feb. 15 during 1975-2015 under scenario 1. Average of recruitment from 1984 to 2016 was used to estimate  $B_{MSY}$ . Pot and trawl handling mortality rates were assumed to be 0.2 and 0.8, respectively.

## Appendix A. Description of the Bristol Bay Red King Crab Model

### a. Model Description

#### i. Population model

The original LBA model was described in detail by Zheng et al. (1995a, 1995b) and Zheng and Kruse (2002). Crab abundances by carapace length and shell condition in any one year are modeled to result from abundances in the previous year minus catch and handling and natural mortalities, plus recruitment, and additions to or losses from each length class due to growth:

$$N_{l,t+1}^s = \sum_{l'=1}^l \{ P_{l',t}^s [(N_{l',t}^s + O_{l',t}^s) e^{-M_{l'}^s} - (C_{l',t}^s + D_{l',t}^s) e^{(y_t-1)M_{l'}^s} - T_{l',t}^s e^{(j_t-1)M_{l'}^s}] m_{l',t}^s \} + R_{t+1}^s U_l^s \quad (A1)$$

$$O_{l,t+1}^s = [(N_{l,t}^s + O_{l,t}^s) e^{-M_l^s} - (C_{l,t}^s + D_{l,t}^s) e^{(y_t-1)M_l^s} - T_{l,t}^s e^{(j_t-1)M_l^s}] (1 - m_{l,t}^s)$$

where  $N_{l,t}^s$  is the number of new shell crab of sex  $s$  in length-class  $l$  at the start of year  $t$ ,  $O_{l,t}^s$  the number of old shell crab of sex  $s$  in length-class  $l$  at the start of year  $t$ ,  $P_{l',t}^s$  the proportion during year  $t$  of animals of sex  $s$  in length-class  $l'$  which grow into length-class  $l$  given that they moulted,  $M_{l'}^s$  the rate of natural mortality on animals of sex  $s$  during year  $t$ ,  $m_{l',t}^s$  the probability that an animal of sex  $s$  in length-class  $l$  will moult during year  $t$ ,  $R_{t+1}^s$  the recruitment [to the model] of animals of sex  $s$  during year  $t$ ,  $U_l^s$  the proportion of recruits of sex  $s$  which recruit to length-class  $l$ ,  $C_{l,t}^s$  the retained catch (in numbers) of animals of sex  $s$  in length-class  $l$  during year  $t$ ,  $D_{l,t}^s$  the discarded catch of animals of sex  $s$  in length-class  $l$  during year  $t$  in the directed fishery and the trawl fishery,  $T_{l,t}^s$  the discarded catch of animals of sex  $s$  in length-class  $l$  during year  $t$  in the Tanner crab fishery,  $y_t$  the time in years between survey and the directed pot and groundfish trawl fisheries during year  $t$ , and  $j_t$  the time in years between survey and the Tanner fishery during year  $t$ .

The minimum carapace length for both males and females is set at 65 mm, and crab abundance is modeled with a length-class interval of 5 mm. The last length class includes all crab  $\geq 160$ -mm CL for males and  $\geq 140$ -mm CL for females. Thus, length classes/groups are 20 for males and 16 for females. Since females moult annually (Powell 1967), females have only the first part of the equation (A1).

The growth increment is assumed to be gamma distributed with mean which depends linearly on pre-moult length, i.e.:

$$P_{l',t}^s = \int_{L_l - \Delta L/2}^{L_l + \Delta L/2} \frac{x^{\alpha_{l',t}^s} e^{x/\beta^s}}{(\beta^s)^{\alpha_{l',t}^s} \Gamma(\alpha_{l',t}^s)} dx \quad \alpha_{l',t}^s \beta^s = a_t^s + b_t^s L_l \quad (A2)$$

where  $L_l$  is the mid-point of length-class  $l$ ,  $\Delta L$  the width of each size-class (5 mm carapace length),  $a_t^s, b_t^s$  the parameters of the length-growth increment relationship for sex  $s$  and year  $t$ , and  $\beta^s$  the parameter determining the variance of the growth increment. Growth is time-invariant for males, and specified for three time-blocks for females (1968-82; 1983-93; 1994-2016) based on changes to the size at maturity for females. The probability of moulting as a function of length for males is given by an inverse logistic function, i.e.:

$$m_l = \frac{1}{1 + e^{\tilde{\beta}(L_l - L_{50})}} \quad (\text{A3})$$

where  $\tilde{\beta}, L_{50}$  are the parameters which determine the relationship between length and the probability of moulting.

Recruitment is defined as recruitment to the model and survey gear rather than recruitment to the fishery. Recruitment is separated into a time-dependent variable,  $R_{t+1}^s$ , and size-dependent variables,  $U_l^s$ , representing the proportion of recruits belonging to each length class.  $R_{t+1}^s$  is assumed to consist of crab at the recruiting age with different lengths and thus represents year class strength for year  $t$ . The proportion of recruits by length-class,  $U_l^s$ , is described using a gamma distribution with parameters  $\alpha_l^s$  and  $\beta_l^s$ . Because of different growth rates, recruitment is estimated separately for males and females under a constraint of approximately equal sex ratios of recruitment over time.

## *ii. Catches and Fisheries Selectivities*

Before 1990, no observed bycatch data were available in the directed pot fishery; the crab that were discarded and died in those years were estimated as the product of handling mortality rate, legal harvest rates, and mean length-specific selectivities. It is difficult to estimate bycatch from the Tanner crab fishery before 1991. A reasonable index to estimate bycatch fishing mortalities is potlifts of the Tanner crab fishery within the distribution area of Bristol Bay red king crab. Thus, bycatch fishing mortalities from the Tanner crab fishery before 1991 were estimated to be proportional to the smoothing average of potlifts east of 163° W. The smoothing average is equal to  $(P_{t-2}+2P_{t-1}+3P_t)/6$  for the potlifts in year  $t$ . The smoothing process not only smoothes the annual number of potlifts, it also indexes the effects of lost pots during the previous years.

The catch (by sex) in numbers by the directed fishery and the groundfish trawl fishery is:

$$G_{l,t}^s = (N_{l,t}^s + O_{l,t}^s) e^{-y_t M_t^s} (1 - e^{-F_{l,t}^s}) \quad (\text{A4})$$

where  $F_{l,t}^s$  is the fishing mortality rate during year  $t$  on animals of sex  $s$  in length-class  $l$  due to the directed fishery and the groundfish trawl fishery:

$$F_{l,t}^s = \begin{cases} S_l^{\text{dir.land}} F_t^{\text{dir}} + (S_l^{\text{dir.disc,mal}} + h_t \phi S_{l,t}^{\text{dir.land}}) F_t^{\text{disc,mal}} + S_l^{\text{trawl}} F_t^{\text{trawl}} & \text{if } s = \text{mal} \\ S_l^{\text{dir.disc,fem}} F_t^{\text{disc,fem}} + S_l^{\text{trawl}} F_t^{\text{trawl}} & \text{if } s = \text{fem} \end{cases} \quad (\text{A5})$$

where  $s_l^{\text{dir,land}}$  is the selectivity pattern for the landings by the directed fishery,  $s_l^{\text{dir,disc},s}$  the selectivity pattern for the discards in the directed fishery by sex,  $s_l^{\text{trawl}}$  the selectivity pattern for the bycatch in the groundfish trawl fishery,  $F_t^{\text{dir}}$  the fully-selected fishing mortality during year  $t$  (on males),  $F_t^{\text{disc},s}$  the fully-selected fishing mortality on animals of sex  $s$  during year  $t$  related to discards in the directed fishery,  $F_t^{\text{trawl}}$  the fully-selected fishing mortality due to the groundfish trawl fishery,  $\phi$  the handling mortality (the proportion of animals which die due to being returned to the water following capture), and  $h_t$  the rate of high-grading during year  $t$ , i.e. discards of animals which can be legally-retained by the directed pot fishery (non-zero only for 2005-2014).

There are no landings of females in a male-only fishery, while the landings  $C$  of males in the directed fishery and discards  $D$  of males in the directed and groundfish fisheries are:

$$\begin{aligned} C_{l,t}^{\text{mal}} &= (N_{l,t}^{\text{mal}} + O_{l,t}^{\text{mal}}) e^{-y_t M_t^{\text{mal}}} (1 - e^{-s_l^{\text{dir,land}} F_t^{\text{dir}}}) \\ D_{l,t}^{\text{mal}} &= G_{l,t}^{\text{mal}} - C_{l,t}^{\text{mal}} \end{aligned} \quad (\text{A6})$$

The catch (by sex) in numbers by the Tanner crab fishery in length-class  $l$  during year  $t$  is given by:

$$T_{l,t}^s = (N_{l,t}^s + O_{l,t}^s) e^{-j_t M_t^s} e^{-F_{l,t}^s} (1 - e^{-\tilde{F}_{l,t}^s}) \quad (\text{A7})$$

where  $\tilde{F}_{l,t}^s$  is the fishing mortality rate during year  $t$  on animals of sex  $s$  in length-class  $l$  due to the Tanner crab fishery:

$$\tilde{F}_{l,t}^s = S_l^{\text{Tanner},s} F_t^{\text{Tanner},s} \quad (\text{A8})$$

where  $S_l^{\text{Tanner},s}$  is the selectivity pattern for the discards in the Tanner crab fishery by sex, and,  $F_t^{\text{Tanner},s}$  the fully-selected fishing mortality during year  $t$  on animals of sex  $s$  during year  $t$  due to this fishery.

For scenario 2, discarded female bycatch in numbers is separated into immature and mature bycatches. The female bycatches in the directed and trawl fisheries in length-class  $l$  and during year  $t$ ,  $D_{l,t}^i$  and  $D_{l,t}^m$ , and  $T_{l,t}^i$  and  $T_{l,t}^m$ , are:

$$\begin{aligned} D_{l,t}^i &= N_{l,t}^i e^{-y_t M_t^{\text{fem}}} (1 - e^{-F_{l,t}^{\text{fem}}}) \\ D_{l,t}^m &= N_{l,t}^m e^{-y_t M_t^{\text{fem}}} (1 - e^{-F_{l,t}^{\text{fem}}}) \end{aligned} \quad (\text{A9})$$

The bycatches (by maturity) in numbers by the Tanner crab fishery in length-class  $l$  during year  $t$  for scenario 2 are given by:

$$\begin{aligned} T_{l,t}^i &= N_{l,t}^i e^{-j_t M_t^{\text{fem}}} e^{-F_{l,t}^{\text{fem}}} (1 - e^{-\tilde{F}_{l,t}^{\text{fem}}}) \\ T_{l,t}^m &= N_{l,t}^m e^{-j_t M_t^{\text{fem}}} e^{-F_{l,t}^{\text{fem}}} (1 - e^{-\tilde{F}_{l,t}^{\text{fem}}}) \end{aligned} \quad (\text{A10})$$

Retained selectivity,  $s^{\text{dir.land}}$ , selectivity for females in the directed fishery,  $s^{\text{dir.disc.fem}}$ , selectivity for males and females in the groundfish trawl trawl,  $s^{\text{trawl}}$ , and selectivity for males and females in the Tanner crab fishery,  $s^{\text{Tanner,s}}$ , are all assumed to be logistic functions of length:

$$S_l^{\text{type}} = \frac{I}{I + e^{-\beta^{\text{type}}(l - L_{50}^{\text{type}})}} \quad (\text{A11})$$

Different sets of parameters ( $\beta$ ,  $L_{50}$ ) are estimated for retained males, female pot bycatch, male and female trawl bycatch, and discarded males and females from the Tanner crab fishery.

Male pot bycatch selectivity in the directed fishery is modeled by two linear functions:

$$\begin{aligned} s_l &= \varphi + \kappa l, \quad \text{if } l < 135 \text{ mm CL}, \\ s_l &= s_{l-1} + 5\gamma, \quad \text{if } l > 134 \text{ mm CL} \end{aligned} \quad (\text{A12})$$

where  $\varphi$ ,  $\kappa$ ,  $\gamma$  are parameters.

### iii. Trawl Survey Selectivities

Trawl survey selectivities are estimated as

$$S_{l,t}^s = \frac{Q}{I + e^{-\beta_t^s(l - L_{50,t}^s)}} \quad (\text{A13})$$

with different sets of parameters ( $\beta$ ,  $L_{50}$ ) estimated for males and females as well as two different periods (1975-81 and 1982-15). Survey selectivity for the first length group (67.5 mm) was assumed to be the same for both males and females, so only three parameters ( $\beta$ ,  $L_{50}$  for females and  $L_{50}$  for males) were estimated in the model for each of the four periods. Parameter  $Q$  was called the survey catchability that was estimated based on a trawl experiment by Weinberg et al. (2004; Figure A1).  $Q$  was assumed to be constant over time.

Assuming that the BSFRF survey caught all crab within the area-swept, the ratio between NMFS abundance and BSFRF abundance is a capture probability for the NMFS survey net. The Delta method was used to estimate the variance for the capture probability. A maximum likelihood method was used to estimate parameters for a logistic function as an estimated capture probability curve (Figure A1). For a given size, the estimated capture probability is smaller based on the BSFRF survey than from the trawl experiment, but the  $Q$  value is similar between the trawl experiment and the BSFRF surveys (Figure A1). Because many small-sized crab are likely in the shallow water areas that are not accessible for the trawl survey, NMFS trawl survey selectivity consists of capture probability and crab availability.

**b. Software Used:** AD Model Builder (Fournier et al. 2012).

**c. Likelihood Components**

A maximum likelihood approach was used to estimate parameters. For length compositions ( $p_{l,t,s,sh}$ ), the likelihood functions are :

$$Rf = \prod_{l=1}^L \prod_{t=1}^T \prod_{s=1}^2 \prod_{sh=1}^2 \frac{\left\{ \exp \left[ - \frac{(p_{l,t,s,sh} - \hat{p}_{l,t,s,sh})^2}{2\sigma^2} \right] + 0.01 \right\}}{\sqrt{2\pi\sigma^2}}$$

$$\sigma^2 = [\hat{p}_{l,t,s,sh} (1 - \hat{p}_{l,t,s,sh}) + 0.1/L]/n \quad (A14)$$

where  $L$  is the number of length groups,  $T$  the number of years, and  $n$  the effective sample size, which was estimated for trawl survey and pot retained catch and bycatch length composition data from the directed pot fishery, and was assumed to be 50 for groundfish trawl and Tanner crab fisheries bycatch length composition data.

The weighted negative log likelihood functions are:

$$\begin{aligned} \text{Length composition : } & - \sum \ln(Rf_i) \\ \text{Biomasses other than survey : } & \lambda_j \sum [\ln(C_t / \hat{C}_t)^2] \\ \text{NMFS survey biomass : } & \sum [\ln(B_t / \hat{B}_t)^2 / (2 \ln(CV_t^2 + 1))] \\ \text{BSFRF mature males : } & \sum [\ln(\ln(CV_t^2 + 1))^{0.5} + \ln(B_t / \hat{B}_t)^2 / (2 \ln(CV_t^2 + 1))] \\ R \text{ variation : } & \lambda_R \sum [\ln(R_t / \bar{R})^2] \\ R \text{ sex ratio : } & \lambda_s [\ln(\bar{R}_M / \bar{R}_F)^2] \\ \text{Trawl bycatch fishing mortality : } & \lambda_t [\ln(F_{t,t} / \bar{F}_t)^2] \\ \text{Pot female bycatch fishing mortality : } & \lambda_p [\ln(F_{t,f} / \bar{F}_f)^2] \\ \text{Trawl survey catchability : } & (Q - \hat{Q})^2 / (2\sigma^2) \end{aligned} \quad (A15)$$

where  $R_t$  is the recruitment in year  $t$ ,  $\bar{R}$  the mean recruitment,  $\bar{R}_M$  the mean male recruitment,  $\bar{R}_F$  the mean female recruitment,  $\bar{F}_t$  the mean trawl bycatch fishing mortality,  $\bar{F}_f$  the mean pot female bycatch fishing mortality,  $Q$  summer trawl survey catchability, and  $\sigma$  the estimated standard deviation of  $Q$  (all scenarios) or each of six growth increment parameters for scenario 2.

For BSFRF total survey biomass,  $CV$  is the survey  $CV$  plus  $AV$ , where  $AV$  is additional  $CV$  and estimated in the model.

Weights  $\lambda_j$  are assumed to be 500 for retained catch biomass, and 100 for all bycatch biomasses, 2 for recruitment variation, 10 for recruitment sex ratio, 0.2 for pot female bycatch fishing mortality, and 0.1 for trawl bycatch fishing mortality. These  $\lambda_j$  values represent prior assumptions about the accuracy of the observed catch biomass data.

#### **d. Population State in Year 1.**

The total abundance and proportions for the first year are estimated in the model.

#### **e. Parameter estimation framework:**

##### i. Parameters estimated independently

Basic natural mortality, length-weight relationships, and mean growth increments per molt were estimated independently outside of the model. Mean length of recruits to the model depends on growth and was assumed to be 72.5 for both males and females. High grading parameters  $h_t$  were estimated to be 0.2785 in 2005, 0.0440 in 2006, 0.0197 in 2007, 0.0198 in 2008, 0.0337 in 2009, 0.0153 in 2010, 0.0113 in 2011, 0.0240 in 2012, 0.0632 in 2013, 0.1605 in 2014, and 0.07 in 2015, based on the proportions of discarded legal males to total caught legal males. Handling mortality rates were set to 0.2 for the directed pot fishery, 0.25 for the Tanner crab fishery, and 0.8 for the trawl fisheries.

##### **(1). Natural Mortality**

Based on an assumed maximum age of 25 years and the 1% rule (Zheng 2005), basic  $M$  was estimated to be 0.18 for both males and females. Natural mortality in a given year,  $M_t$ , equals to  $M + Mm_t$  (for males) or  $M + Mf_t$  (females). One value of  $Mm_t$  during 1980-1985 was estimated and two values of  $Mf_t$  during 1980-1984 and 1976-79, 1985-93 were estimated in the model for scenarios 1, 1n and 2.

##### **(2). Length-weight Relationship**

Length-weight relationships for males and females were as follows:

$$\text{Immature Females: } W = 0.000408 L^{3.127956}$$

$$\text{Ovigerous Females: } W = 0.003593 L^{2.666076} \quad (\text{A16})$$

$$\text{Males: } W = 0.0004031 L^{3.141334}$$

where  $W$  is weight in grams, and  $L$  CL in mm.

##### **(3). Growth Increment per Molt**

A variety of data are available to estimate male mean growth increment per molt for Bristol Bay RKC. Tagging studies were conducted during the 1950s, 1960s and 1990s, and mean growth increment per molt data from these tagging studies in the 1950s and 1960s were analyzed by Weber and Miyahara (1962) and Balsiger (1974). Modal analyses were conducted for the data during 1957-1961 and the 1990s (Weber 1967; Loher et al. 2001). Mean growth increment per molt may be a function of body size and shell condition and vary over time (Balsiger 1974; McCaughran and Powell 1977); however, for simplicity, mean growth increment per molt was assumed to be only a function of body size in the models. Tagging data were used to estimate mean growth increment per molt as a function of pre-molt length for males (Figure A2). The results from modal analyses of 1957-1961 and the 1990s were used to estimate mean growth increment per molt for immature females during 1975-1993 and 1994-2016, respectively, and the data presented in Gray (1963) were used to estimate those for mature females for

scenarios 1, 1n and 2 (Figure A2). To make a smooth transition of growth increment per molt from immature to mature females, weighted growth increment averages of 70% and 30% at 92.5 mm CL pre-molt length and 90% and 10% at 97.5 mm CL were used, respectively, for mature and immature females during 1983-1993. These percentages are roughly close to the composition of maturity. During 1975-1982, females matured at a smaller size, so the growth increment per molt as a function of length was shifted to smaller increments. Likewise, during 1994-2016, females matured at a slightly higher size, so the growth increment per molt was shifted to high increments for immature crab (Figure A2). Once mature, the growth increment per molt for male crab decreases slightly and annual molting probability decreases, whereas the growth increment for female crab decreases dramatically but annual molting probability remains constant at 1.0 (Powell 1967).

#### **(4). Sizes at Maturity for Females**

The NMFS collected female reproductive condition data during the summer trawl surveys. Mature females are separated from immature females by a presence of egg clutches or egg cases. Proportions of mature females at 5-mm length intervals were summarized and a logistic curve was fitted to the data each year to estimate sizes at 50% maturity. Sizes at 50% maturity are illustrated in Figure A3 with mean values for three different periods (1975-82, 1983-93, and 1994-2015).

#### **(5). Sizes at Maturity for Males**

Although size at sexual maturity for Bristol Bay red king crab males has been estimated (Paul et al. 1991), there are no data for estimating size of functional maturity collected in the natural environment. Sizes at functional maturity for Bristol Bay male RKC have been assumed to be 120 mm CL (Schmidt and Pengilly 1990). This is based on mating pair data collected off Kodiak Island (Figure A4). Sizes at maturity for Bristol Bay female RKC are about 90 mm CL, about 15 mm CL less than Kodiak female RKC (Pengilly et al. 2002). The size ratio of mature males to females is 1.3333 at sizes at maturity for Bristol Bay RKC, and since mature males grow at much larger increments than mature females, the mean size ratio of mature males to females is most likely larger than this ratio. Size ratios of the large majority of Kodiak mating pairs were less than 1.3333, and in some bays, only a small proportion of mating pairs had size ratios above 1.3333 (Figure A4).

In the laboratory, male RKC as small as 80 mm CL from Kodiak and Southeast Alaska can successfully mate with females (Paul and Paul 1990). But few males less than 100 mm CL were observed to mate with females in the wild. Based on the size ratios of males to females in the Kodiak mating pair data, setting 120 mm CL as a minimum size of functional maturity for Bristol Bay male RKC is proper in terms of managing the fishery.

#### **(6). Potential Reasons for High Mortality during the Early 1980s**

Bristol Bay red king crab abundance had declined sharply during the early 1980s. Many factors have been speculated for this decline: (i) completely wiped out by fishing: the directed pot fishery, the other directed pot fishery (Tanner crab fishery), and bottom

trawling; and (ii) high fishing and natural mortality. With the survey abundance, harvest rates in 1980 and 1981 were among the highest, thus the directed fishing definitely had a big impact on the stock decline, especially legal and mature males. However, for the sharp decline during 1980-1984 for males, 3 out of 5 years had low mature harvest rates. During the 1981-1984 decline for females, 3 out of 4 years had low mature harvest rates. Also pot catchability for females and immature males are generally much lower than for legal males, so the directed pot fishing alone cannot explain the sharp decline for all segments of the stock during the early 1980s.

Red king crab bycatch in the eastern Bering Sea Tanner crab fishery is another potential factor (Griffin et al. 1983). The main overlap between Tanner crab and Bristol Bay red king crab is east of 163° W. No absolute red king crab bycatch estimates are available until 1991. So there are insufficient data to fully evaluate the impact. Retained catch and potlifts from the eastern Bering Sea Tanner crab fishery are illustrated in Figure A5. The observed red king crab bycatch in the Tanner crab fishery during 1991-1993 and total potlifts east of 163° W during 1968 to 2005 were used to estimate the bycatch mortality in the current model. Because winter sea surface temperatures and air temperatures were warmer (which means a lower handling mortality rate) and there were fewer potlifts during the early 1980s than during the early 1990s, bycatch in the Tanner crab fishery is unlikely to have been a main factor for the sharp decline of Bristol Bay red king crab.

Several factors may have caused increases in natural mortality. Crab diseases in the early 1980s were documented by Sparks and Morado (1985), but inadequate data were collected to examine their effects on the stock. Stevens (1990) speculated that senescence may be a factor because many crab in the early 1980s were very old due to low temperatures in the 1960s and early 1970s. The biomass of the main crab predator, Pacific cod, increased about 10 times during the late 1970s and early 1980s. Yellowfin sole biomass also increased substantially during this period. Predation is primarily on juvenile and molting/softshell crab. But we lack stomach samples in shallow waters (juvenile habitat) and during the period when red king crab molt. Also cannibalism occurs during molting periods for red king crab. High crab abundance in the late 1970s and early 1980s may have increased the occurrence of cannibalism.

Overall, the likely causes for the sharp decline in the early 1980s are combinations of the above factors, such as pot fisheries on legal males, bycatch, and predation on females and juvenile and sublegal males, senescence for older crab, and disease for all crab. In our model, we estimated one mortality parameter for males and another for females during 1980-1984. We also estimated a mortality parameter for females during 1976-1979 and 1985-1993. These three mortality parameters are additional to the basic natural mortality of  $0.18\text{yr}^{-1}$ , all directed fishing mortality, and non-directed fishing mortality. These three mortality parameters could be attributed to natural mortality as well as undocumented non-directed fishing mortality. The model fit the data much better with these three parameters than without them.

## ii. Parameters estimated conditionally

The following model parameters were estimated for male and female crab: total recruits

for each year (year class strength  $R_t$  for  $t = 1976$  to  $2016$ ), total abundance in the first year (1975), growth parameter  $\beta$ , and recruitment parameter  $\beta_r$  for males and females separately. Molting probability parameters  $\beta$  and  $L_{50}$  were also estimated for male crab. Estimated parameters also include  $\beta$  and  $L_{50}$  for retained selectivity,  $\beta$  and  $L_{50}$  for pot-discarded female selectivity,  $\beta$  and  $L_{50}$  for pot-discarded male and female selectivities from the eastern Bering Sea Tanner crab fishery,  $\beta$  and  $L_{50}$  for groundfish trawl discarded selectivity,  $\varphi$ ,  $\kappa$  and  $\gamma$  for pot-discarded male selectivity, and  $\beta$  for trawl survey selectivity and  $L_{50}$  for trawl survey male and females separately. The NMFS survey catchabilities  $Q$  for some scenarios were also estimated. Three selectivity parameters were estimated for the survey data from the Bering Fisheries Research Foundation. Annual fishing mortalities were also estimated for the directed pot fishery for males (1975-2015), pot-discarded females from the directed fishery (1990-2015), pot-discarded males and females from the eastern Bering Sea Tanner crab fishery (1991-93, 2013-15), and groundfish trawl discarded males and females (1976-2015). Three additional mortality parameters for  $Mm_t$  and  $Mf_t$  were also estimated. Some estimated parameters were constrained in the model. For example, male and female recruitment estimates were forced to be close to each other for a given year.

**f. Definition of model outputs.**

- i. Biomass: two population biomass measurements are used in this report: total survey biomass (crab >64 mm CL) and mature male biomass (males >119 mm CL). Mating time is assumed to Feb. 15.
- ii. Recruitment: new entry of number of males in the 1<sup>st</sup> seven length classes (65- 99 mm CL) and new entry of number of females in the 1<sup>st</sup> five length classes (65-89 mm CL).
- iii. Fishing mortality: full-selected instantaneous annual fishing mortality rate at the time of fishery.

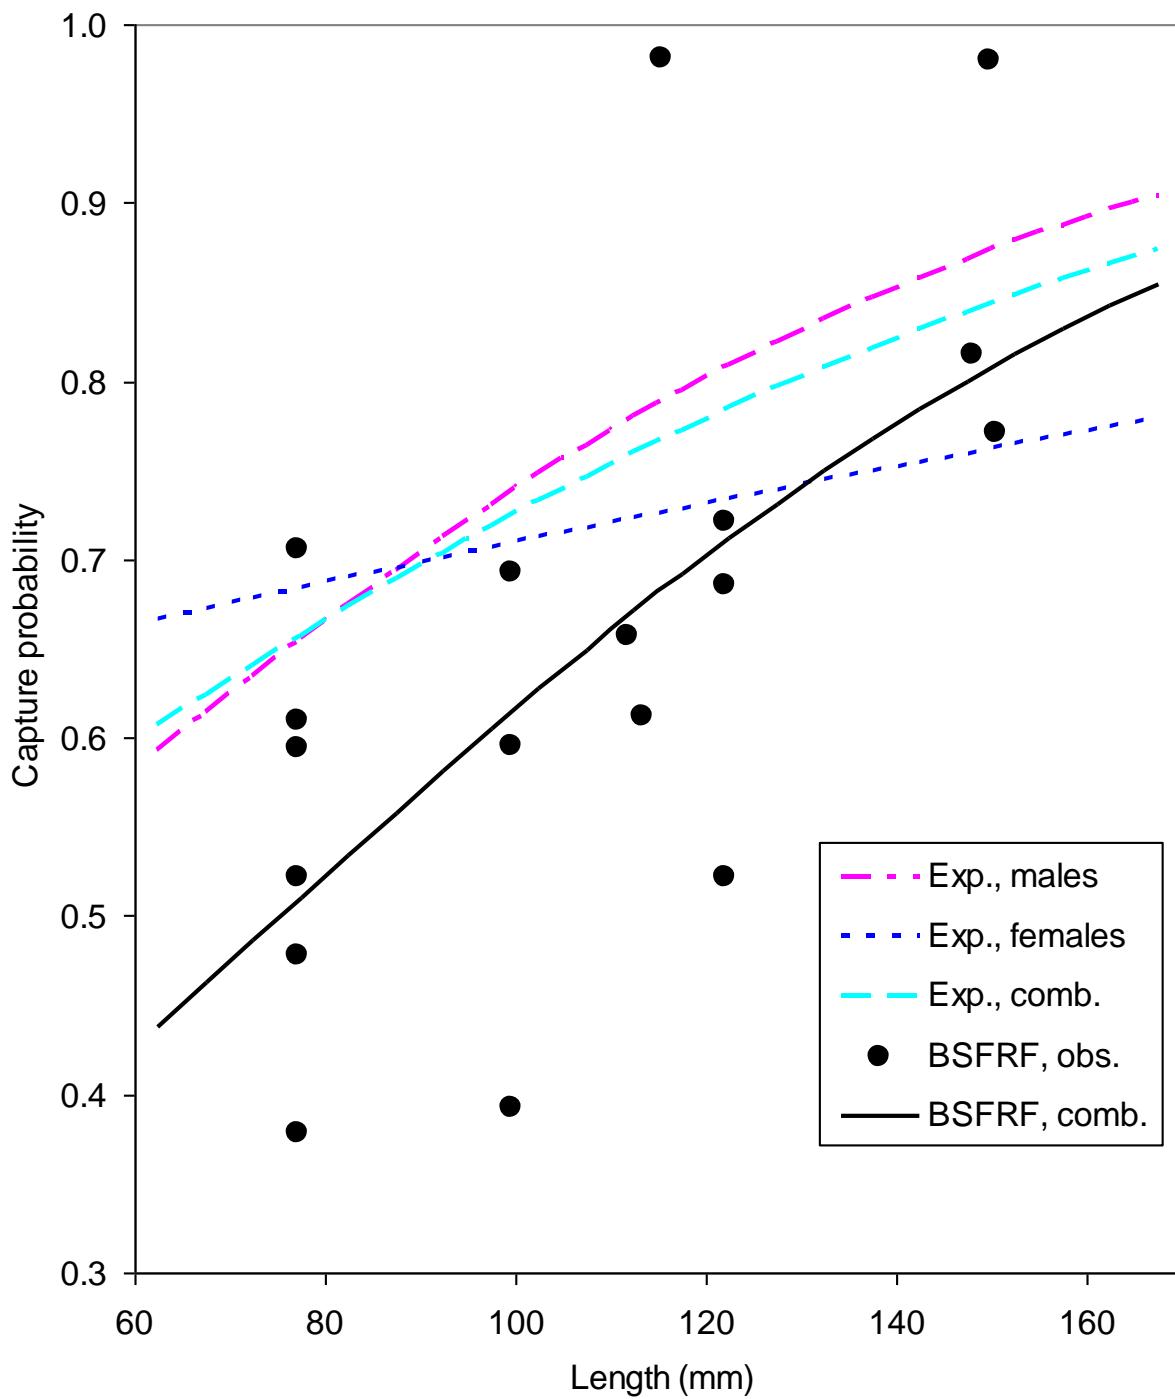

Figure A1. Estimated capture probabilities for NMFS Bristol Bay red king crab trawl surveys by Weinberg et al. (2004) and the Bering Sea Fisheries Research Foundation surveys.

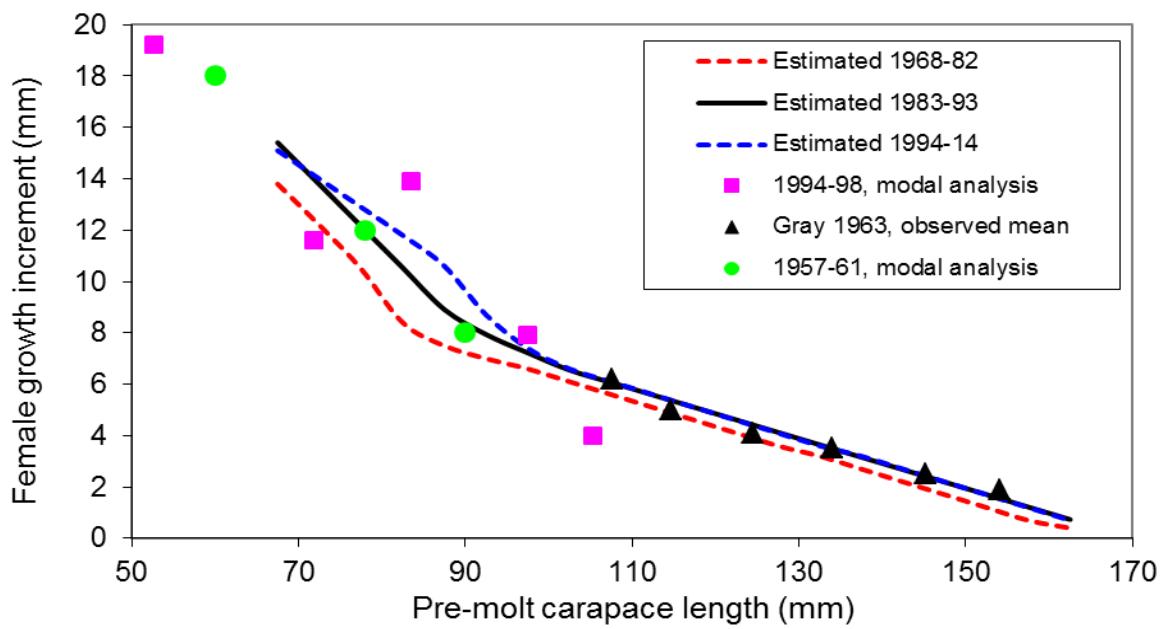

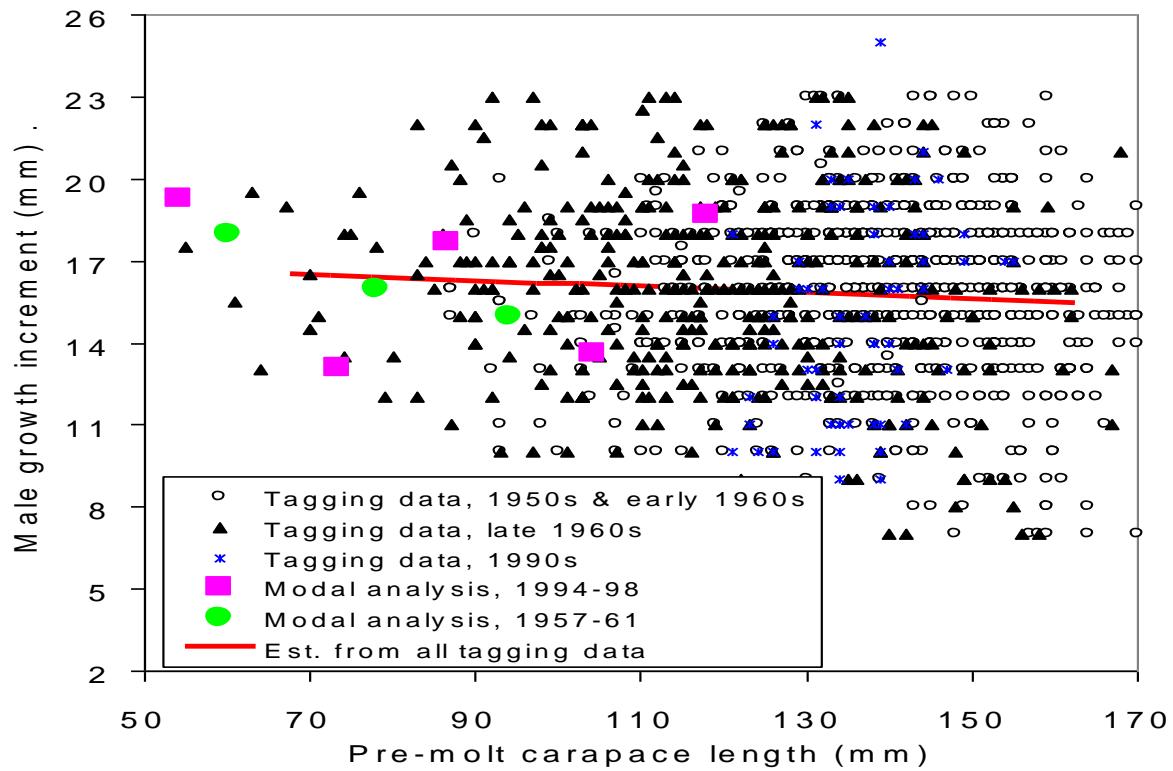

Figure A2. Mean growth increments per molt for Bristol Bay red king crab. Note: “tagging”---based on tagging data; “mode”---based on modal analysis. The female growth increments per molt are for scenarios 1, 1n and 2.

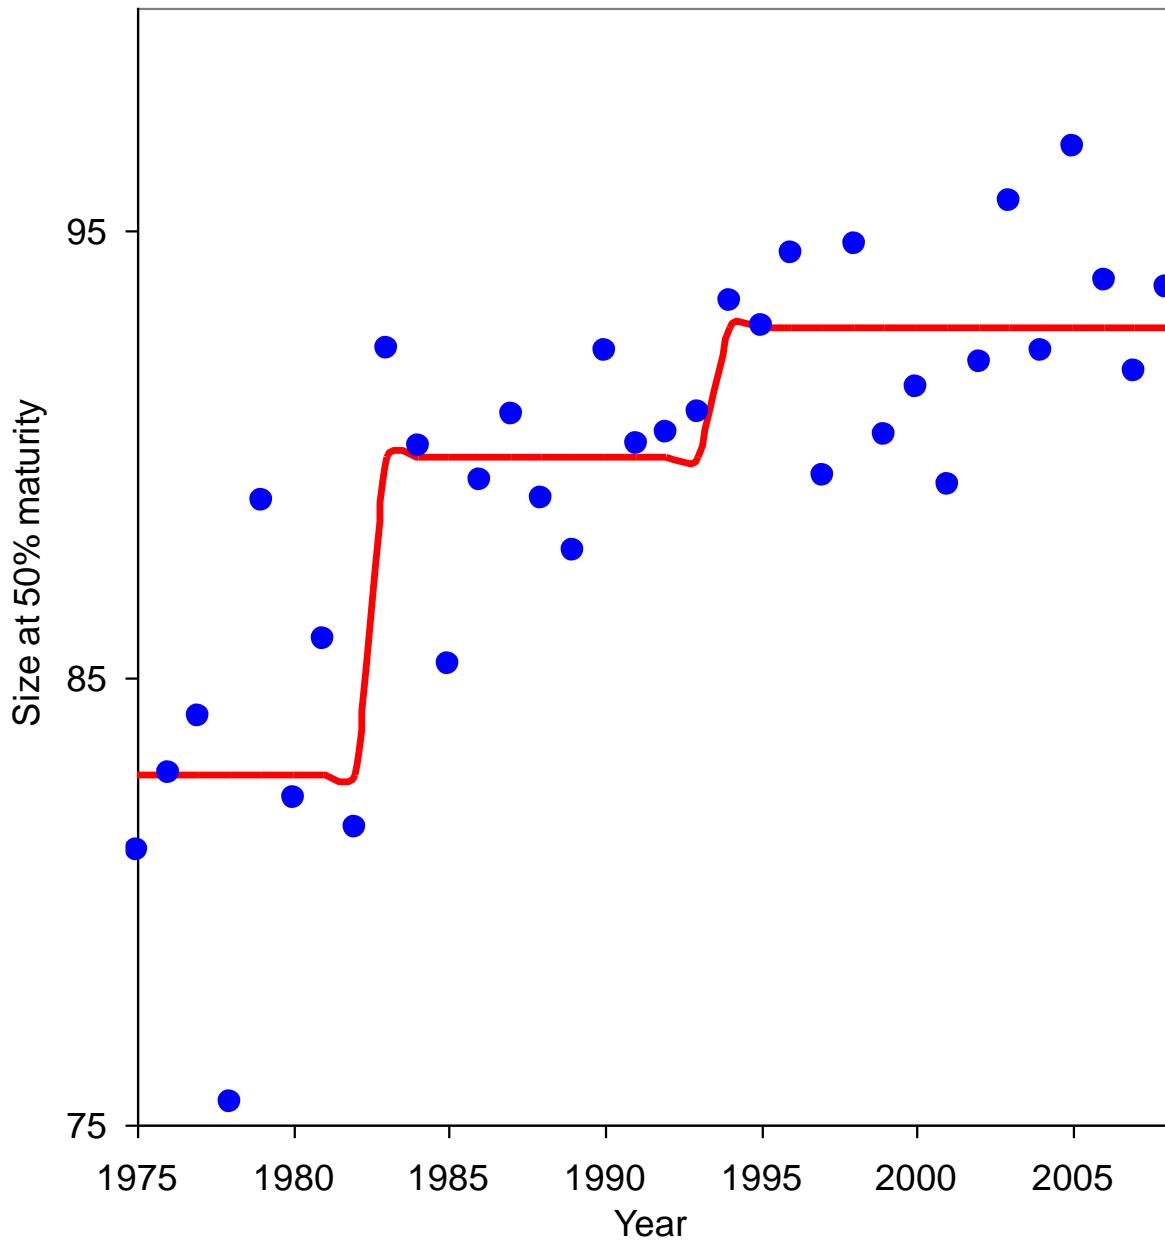

Figure A3. Estimated sizes at 50% maturity for Bristol Bay female red king crab from 1975 to 2008. Averages for three periods (1975-82, 1983-93, and 1994-08) are plotted with a line.

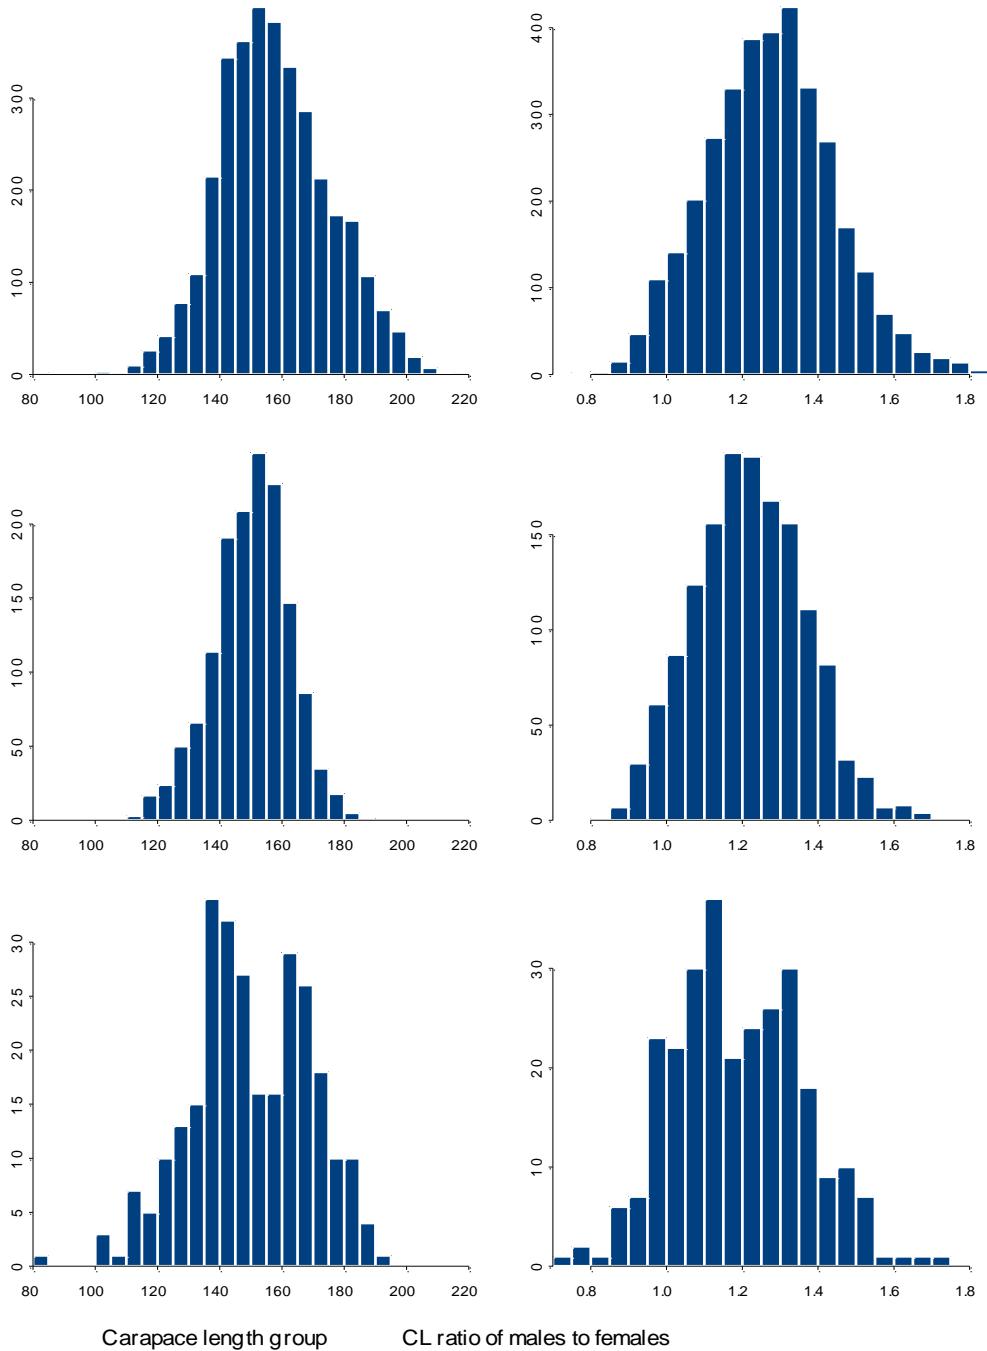

Figure A4. Histograms of carapace lengths (CL) and CL ratios of males to females for male shell ages  $\leq 13$  months of red king crab males in grasping pairs; Powell's Kodiak data. Upper plot: all locations and years pooled; middle plot: location 11; lower plot: locations 4 and 13. Sizes at maturity for Kodiak red king crab are about 15 mm larger than those for Bristol Bay red king crab. (Doug Pengilly, ADF&G, pers. comm.).
